ABSTRACT
Mucoadhesive drug delivery systems interact with the mucus layer covering the mucosal epithelial surface and increase the residence time of the dosage form at the absorption site. The drugs which have local action or those which have maximum absorption in gastrointestinal tract (GIT) require increased duration of stay in GIT. Thus, mucoadhesive dosage forms are advantageous in increasing the drug plasma concentrations and also therapeutic activity. Silymarin (SLM) is an effective hepatoprotective drug used in therapeutic practice today. However, its absorption is in stomach and needs to be retained in the same for prolonged period. So SLM is suitable candidate to develop into mucoadhesive drug delivery system. The objective of the present study was to formulate mucoadhesive microspheres of Silymarin and carry out evaluation of the formulated microspheres. In the present study, five formulations of microspheres with variable concentrations of mucoadhesive polymer and film forming polymer (HPMC & EC) were prepared by Emulsification solvent evaporation method and evaluated for physico-chemical, preformulation and formulation parameters. Compatibility studies proved that there was no interaction between Silymarin and polymers used. Silymarin microspheres were smooth and spherical in nature, which was confirmed by SEM. The in vitro performance of SLM microspheres showed controlled release depending on the concentration of mucoadhesive polymer. Finally it can be concluded that mucoadhesive microspheres encapsulated with optimum concentration of mucoadhesive polymer and film forming polymer showed better results in all the evaluated parameters making it a potential candidate for controlled release drug delivery system.

Keywords: Mucoadhesive Microspheres, Controlled Release, HPMC, EC.

INTRODUCTION
Oral route of drug administration constitutes the most convenient and preferred means of drug delivery to systemic circulation in the body. However oral administration of most of the drugs in conventional dosage forms has short-term limitations due to their inability to restrain and localize the system at gastrointestinal tract. In order to circumvent this problem, it has been proposed, to associate drugs to polymeric particulate systems because of their propensity to interact with the mucosal surface. This property is not only used for the local targeting of drugs but also for a better control of systemic delivery. Thus the real issue in the development of oral controlled release drug delivery systems is to provide drug release in an amount sufficient to maintain the therapeutic drug level over extended period of time, through the predominantly controlled release profiles.
by special technological construction and design of the system itself. The idea of using bioadhesive polymers to prolong the contact time in the mucosal route of drug delivery was introduced in early 1980s, and since then it has attracted considerable attention from pharmaceutical scientists. The concept of mucoadhesive drug delivery is based on the bioadhesive property of certain polymers that becomes adhesive on hydration and hence can be used for localizing the drugs to a particular region of gastrointestinal tract and to extend the gastric residence time. Once the dosage form sticks to the mucosal surface of gastric tissue, it will reside there until removed by turnover of mucins. Recent advances pertaining to drug delivery systems incorporate different type of polymers within the matrix of drug delivery systems to protect the active ingredient and to induce slow release characteristics. [1-6] 
There has been considerable interest in the field of mucoadhesive drug delivery systems since the immobilization of drug carrying particles at mucosal surface would result in:

1. A prolonged residence time at the site of drug action or absorption. [7]
2. A localization of drug action at the delivery system at a given target site. [8-9]
3. An increase in the drug concentration gradient due to the intense contact of particles with the mucosal. [10]
4. A direct contact with intestinal cells that is the first step before particle absorption.

Microspheres form an important part of novel drug delivery systems. However, the success of these microspheres is limited owing to their short residence time at the site of absorption. It would, therefore, be advantageous to have means for providing an intimate contact of the drug delivery system with the absorbing membranes. This can be achieved by coupling bioadhesion characteristics to microspheres and developing bioadhesive microspheres, [11-16] Bioadhesive microspheres have advantages such as efficient absorption and enhanced bioavailability of drugs owing to a high surface-to-volume ratio, a much more intimate contact with the mucus layer, and specific targeting of drugs to the absorption site. Mucoadhesive microspheres that are retained in the stomach would increase the drug absorption and decrease dosing frequency which provides better patient compliance as compared to conventional dosage forms. [17-19]

In the present work Silymarin (SLM) was chosen as the drug to formulate the gastro retentive drug delivery system like mucoadhesive microspheres. Silymarin (SLM) is one of the most powerful drugs for the hepatic diseases. It is known for its hepatoprotective action against hepatic glutathione depletion induced by ethyl alcohol and paracetamol in animal studies. Silymarin degrades as the pH increases. Hence it is necessary to dissolve it in less pH for the protection of the drug and to reduce the gastric disturbance and more over, the site of absorption of SLM is in the stomach pH. Hence it is suitable to formulate silymarin as mucoadhesive microspheres to reduce frequency of dosing, prevent the drug from degradation in the intestinal pH and increases its shorter biological half life. [20-21] 
The SLM is degraded as the pH increases so it is necessary to dissolve in the less pH for the protection of the drug and to reduce the gastric disturbance and more over, the site of absorption of SLM is in the stomach pH. Hence it is suitable to formulate SLM as mucoadhesive microspheres to reduce frequency of dosing and to prevent the drug from degradation in the intestinal pH. To overcome inherent drawbacks associated with conventional dosage forms of Silymarin, an attempt is being made to develop an alternative drug delivery system in the form of mucoadhesive microspheres which increases its stability, biological half life and bioavailability in stomach.

MATERIALS & METHODS
Preparation of Mucoadhesive Microspheres of Silymarin: [22-25] For present study, variable concentrations of film coating polymer ethyl cellulose combined with mucoadhesive polymer hydroxy propyl methyl cellulose are used with the active ingredient for preparation of mucoadhesive microspheres. Accurately weighted amount of the Mucoadhesive polymer hydroxy propyl methyl cellulose and film forming polymer ethyl cellulose as shown in Table 1 were dissolved in 50 ml of acetone to form a homogenous polymers solution. Silymarin was then dispersed in it and mixed thoroughly. This organic phase containing drug was slowly poured at 150°C into liquid paraffin (50 ml) containing 1% (w/v) of Span-80 with stirring at 1000 rpm to form a uniform emulsion. Thereafter, it was allowed to attain room temperature and stirring was continued until residual acetone evaporated and smooth-walled, rigid and discrete microspheres were formed. The microspheres were collected by decantation and the product was washed with petroleum ether or n- hexane and dried at room temperature for 3 hours. The microspheres were then stored in a desiccators over fused calcium chloride.

Evaluation of Drug Loaded Mucoadhesive Microspheres
Drug polymer interaction (FTIR) study: [24] Drug polymer interactions were studied by FT-IR spectroscopy. One to 2 mg of Silymarin alone, mixture of drug and polymer, drug loaded microspheres were weighed and mixed properly with potassium bromide and compared to study any interference.
Scanning Electron Microscopy (SEM): Scanning electron microscopy has been used to determine particle size distribution, surface topography, texture, and to examine the morphology of fractured or sectioned surface. Dry Silymarin mucoadhesive microspheres were placed on an electron microscope brass stub and coated with a thin carbon layer. Picture of Silymarin microspheres were taken by random scanning of the stub.

Frequency distribution analysis: The diameter of a sample of mucoadhesive microspheres (300 no) of each formulation was determined using optical microscopy. In order to be able to define a frequency distribution or compare the characteristics of particles with many different diameters, the frequency distribution can be broken down into different size ranges, which can be presented in the form of a histogram.

**Percentage yield:** Percentage practical yield of Silymarin microspheres was calculated to know about percentage yield or efficiency of any method, thus it helps in selection of appropriate method of production. Practical yield was calculated as the weight of Silymarin microspheres recovered from each batch in relation to the sum of starting material. The percentage yield of Silymarin microspheres prepared was determined by using the formula:

\[ \text{Percentage Yield} = \frac{\text{Actual weight of product}}{\text{Total weight of drug and polymer}} \times 100 \]

**Drug Content:**

To determine the drug content and encapsulation efficiency of the mucoadhesive microspheres, 200 mg microspheres were crushed using a porcelain mortar and a pestle, and dispersed in suitable solvent (methanol). The dispersion was sonicated for 15 minutes and left overnight for 24 hrs, then the dispersion was filtered. A 1 ml sample was taken and diluted with suitable solvent (methanol), and drug content assayed using a UV-visible spectrophotometer at \( \lambda_{\text{max}} \) of 287 nm. The drug content of each formulation was recorded as mg/200 mg of microspheres.

**Drug Entrapment Efficiency:** The drug entrapment efficiency of prepared microspheres was determined by using the following equation.

\[ \text{EE} \% = \frac{\text{Actual Drug Content}}{\text{Theoretical Drug Content}} \times 100 \]

**Drug Loading** was calculated as:

\[ \text{DL} \% = \frac{\text{Actual Drug Content}}{\text{Weight of Powdered Microspheres}} \times 100 \]

**Degree of Swelling:** The swell ability of microspheres in physiological media was determined by swelling them in the PBS pH 6.4. Accurately weighed 100 mg of microspheres were immersed in little excess of PBS pH 6.4 for 24 hrs and washed. The degree of swelling was calculated using following formula:

\[ \alpha = \frac{(W_s - W_0)}{W_0} \]

Where \( \alpha \) is the degree of swelling; \( W_0 \) is the weight of microspheres before swelling; \( W_s \) is the weight of microspheres after swelling.

**In vitro Mucoadhesion Studies:** In vitro mucoadhesion studies of microspheres were assessed using falling liquid film technique. A small portion of the sheep intestinal mucosa was mounted on a glass slide and accurately weighed microspheres were sprinkled on the mucosa. This glass slide was kept in desiccator for 15 min to allow the polymer to interact with the membrane and finally placed in the cell that was attached to the outer assembly at an angle of 45°. Phosphate buffer solution pH 6.4, previously warmed to 37 ± 5°C was circulated all over the microspheres and membrane at the rate of 1 ml/min. Washings were collected at different time intervals and microspheres were collected by centrifugation followed by drying at 50°C. The weight of washed out microspheres was determined and percent mucoadhesion was calculated by following formula:

\[ \% \text{ Mucoadhesion} = \frac{(W_0 - W_f) \times 100}{W_0} \]

Where, \( W_0 = \) weight of microspheres applied; \( W_f = \) weight of microspheres leached out.

**In vitro dissolution studies:** The release rate of Silymarin mucoadhesive microspheres was determined by employing USP XXIII apparatus II (Rotating basket method). The dissolution test was performed using 900 ml 0.1N HCl, in 37 ± 0.5°C at 50 rpm. Silymarin mucoadhesive microspheres equivalent to 100 mg of Silymarin was used for the study. At various time points (hourly) 5 ml of the sample solution was withdrawn from the dissolution apparatus for up to 12 hrs, and the samples were replaced with fresh dissolution medium. The samples were filtered and the absorbance was determined at 287nm. Dissolution profiles of the formulations were analyzed by plotting cumulative percentage drug release versus time. The data obtained were also subjected to kinetic treatment to understand release mechanism.

RESULTS & DISCUSSION
In the current research, mucoadhesive microspheres encapsulated with Silymarin were formulated using emulsification solvent evaporation method and evaluated.

FTIR Studies: The physical mixture of drug and polymers showed identical spectrum with respect to the spectrum of the pure silymarin, indicating there is no chemical interaction between the drug molecule and polymers used. (Fig. 1-4)

Scanning Electron Microscopy (SEM): Scanning electron microscopy confirms the outer surface of the formulations was smooth and dense, while the internal surface was porous. The shell of microspheres also showed some porous structure which may be caused by evaporation of solvent entrapped within the shell of microspheres after forming smooth and dense layer.

Particle Size and Frequency Distribution Analysis: The mean particle size of mucoadhesive microspheres was in range of 289.43-387.75μm (Table 2 & Fig. 6). As the ratio of HPMC was increased, the mean particle size of SLM microspheres had also increased. The significant increase may be due to the increase in the viscosity of the droplets. SLM mucoadhesive microspheres having a size range of 200 to 500 µm (Fig 7) with normal frequency distribution was obtained.

Percentage Yield: For different formulations percentage yield was calculated by weighing the microspheres after drying. The percentage yield of mucoadhesive microspheres was in range of 74.28 – 94.54% (Table 2 & Fig. 8).

Percent Encapsulation Efficiency and Percent Drug loading: Entrapment efficiency decreased with increase in the mucoadhesive polymer concentration. From the results it can be inferred that there is a proper distribution of SLM in the microspheres and the deviation were within the acceptable limits. The percent of drug content in the formulations were found to be in the range of 16.17% to 25.06%. The percentage entrapment efficiency was found to be 84.25% to 94.35%. The results obtained are given in Table 2 and their histograms are shown in Fig. 8.

Degree of swelling and Percent Mucoadhesion: Degree of swelling and percentage mucoadhesion of the formulations were carried out and were found to be within the range between 1.03 to 1.74 and 81.23 to 98.91%. Both parameters increased with increase in the concentration of mucoadhesive polymer.

In vitro Dissolution Studies: The in vitro performance of SLM microspheres showed prolonged and controlled release of SLM. The results of the in vitro dissolution studies showed controlled release in a predictable manner. As the mucoadhesive polymer concentration was increased, the drug release from the mucoadhesive microspheres was found to decrease. However, all the formulations had an optimum release at the end of 12th hour. The in vitro release profiles of all the formulations (F1 to F5) are shown in Table 4 and Fig. 9.

Release kinetics of Silymarin Mucoadhesive Microspheres: The slopes and the regression coefficient of determinations (r²) were listed in Table 5. The co-efficient of determination indicated that the release data was best fitted with zero order as-well-as first order kinetics. Higuchi equation explains the diffusion controlled release mechanism. The diffusion exponent ‘n’ values of Korsemeyer-Peppas model was found to be in the range of 0.5 to 0.6 for the SLM mucoadhesive microspheres indicating Non-Fickian release of drug.
From the study it is evident that mucoadhesive microspheres are more promising for controlled release dosage forms. By studying all the results, mucoadhesive microspheres encapsulated with Silymarin can be successfully formulated by emulsification solvent evaporation method. By incorporating mucoadhesive polymer such as HPMC and film forming polymer like ethyl cellulose in the shell of microspheres, the rate of drug release can be modulated in a controlled manner. Therefore formulation F3 containing optimum concentration of mucoadhesive polymer and film forming polymer showed the best appropriate balance between mucoadhesion and controlled release and is considered as the ideal batch of formulation.
