Nutritional quality of processed head and bone flours of Tilapia (Oreochromis mossambicus, Peters 1852) from Parangipettai estuary, South East Coast of India

R.Vignesh*, M Srinivasan
Centre of Advanced Study in Marine Biology, Faculty of Marine Sciences, Annamalai University Parangipettai 608502, Tamilnadu, India

**Objective:** To analyze the proximate composition, fatty acids, amino acids and nutritional composition of flour made from Tilapia (Oreochromis mossambicus) head and bones. **Methods:** Tilapia fish head and bone are the parts with unknown composition. Fish bones and heads were collected, cleaned and dried. The flours were prepared using 14-mesh stainless steel sieve and analysed further. **Results:** The results in 100 g of Tilapia head flour (THF) were composed of moisture [5.89±0.01]%, protein [32.59±0.02]%, total lipids [0.201±0.0002]%, and ash [11.14±0.02]%. The results in 100 g of Tilapia bone flour (TBF) were: moisture [4.22±0.02]%, protein [31.52±0.02]%, total lipids [0.8761±0.0002]%, and ash [0.89±0.01]%.

**Keywords:** Fatty acids, Amino acids, Vitamins and Minerals, Heads, Bones, Predominant, Human diet

1. Introduction

Fishes received increased attention as a potential source of animal protein and essential nutrients for human diets [1]. Fish and fish products are very important sources of income and high market value [2]. Fish has been shown to be the cheapest source of animal protein in Third World Countries [3]. The consumption of fish is allied to health reinforcement because of its richness in proteins of high dietary value; minerals, vitamins and distinguishing lipids. It should be considered that fish tissue presents elevated nutritional significance and therefore is a particularly optional dietary module. In addition, fish are a good source of micro and macro-elements such as calcium, phosphorus, selenium and manganese [4]. Fish lipids are well known to be rich in long-chain (LC) n-3 polyunsaturated fatty acids (LC n-3 PUFA), especially eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) [5].

Earlier research on fish proteins [6-9], has shown that they have bioactive properties and beneficial health effects.
which make them a very interesting alternative for the food industry. Several research groups around the world have been working on converting these wastes into useful food and bioactive ingredients\[9-11\]. Fish mince by products can also be successfully used directly in various food systems and in physically or chemically altered form to produce an array of nutritional and functional products\[12\]. Some studies have shown that FPH prepared from fish byproducts such as bones and heads can contribute to increased water holding capacity in food formulations\[13,14\]. Several studies have indicated that peptides derived from fish by product proteins have antioxidative properties in different oxidative systems\[15,16\]. Fish protein hydrolysates prepared from fish byproducts can also function as immunostimulants, can have anti-carcinogenic effects and anti-anemia activity\[17\]. Researchers have identified and reported specific peptides from animal and fish proteins responsible for ACE inhibition\[11,18,19\]. The other reported bioactivities include antihypertensive, immunomodulatory, neuroactive, antimicrobial, mineral and hormonal regulating properties\[20-22\]. A review by Underland et al\[23\] presented the health effects of different seafood products including fish proteins and FPH from fish byproducts and a review from Kim & Mendis\[24\] discussed the bioactive effects of marine rest raw materials.

Tilapias are the most important fishes cultured both in tropical and subtropical countries. According to the FAO\[25\], the global tilapia aquaculture production in 2008 stood at nearly 2.8 million tons. Tilapia fillets have high protein, low fat, low calorie, and low carbohydrate. Tilapia fillets are also an excellent source of Phosphorus, Niacin, Selenium, Vitamin B12 and Potassium\[26\]. In many countries of the world, the huge quantities of fish waste produced are often discarded into the environment and become a source of pollution. With these facts in mind, the aim of the present study is to evaluate the fatty acid composition and nutrient potential of tilapia heads and bones after processing in the form of flour, with the ultimate goal of its consumption by humans. Tilapias were chosen for this work based on the fact that they have good consumer acceptance, economically viable and are in low fat content\[27\]. They are also the most farmed fish in the tropical and sub-tropical regions of and have been playing an increasingly key role in the nation’s nutrition as source of relatively cheap animal protein. The measurement of some proximate profiles such as protein contents, lipids and moisture contents is often necessary to ensure that they meet the requirements of food regulations and commercial specifications. In many countries the huge quantities of fish waste produced are often discarded into the environment and thus become a source of pollution. There are no intensive studies on fish wastes and their importance is uncared. Thus this study focuses on the evaluation of all possible nutrients from the head and bone flours made from Oreochromis mossambicus. We point out that there are no reports on the nutritive value (fatty acid, amino acid, vitamin and mineral composition) of tilapia fish head and bone flour in either the national or international literature, which prompted us to evaluate its nutritional value. Thus this is the first study which reports the nutritive value of tilapia (Oreochromis mossambicus) byproducts.

2. Materials and methods

2.1. Samples

The fish Tilapia Oreochromis mossambicus (Peters, 1852) used for this study were captured from the Parangipettai estuary (South East Coast of India). Their length ranged as 8.9± 11.2 cm to 17.3 ±18.4 cm and body weight was 12.3±14.8 g to 15.3±21.6 g. The samples i.e. the heads and bones were collected fresh and the flour samples were prepared as follows.

2.2. Sampling

The tilapia heads and bones were separated and washed with filtered water, cleaned with paper towels and dried for 25 minutes. After drying the bones were ground in an endless-screw grinder, placed on trays and dried in an oven for 4 hours at 180 °C. Next, the flour was sieved using a 14–mesh stainless steel sieve. The product obtained, referred to as tilapia fish head and bone flour (THF & TBF), was packed in polyethylene bags, wrapped in aluminum foil after removal of air, and stored in refrigerator at 4°C for later analysis.

2.3. Analytical methods

2.3.1. Moisture and ash content analysis

Proximate composition analyses of the samples were done in triplicate for protein, moisture, lipid and ash contents. The crude protein was determined by the Kjeldahl procedure\[28\]. Moisture was determined by oven drying at 105 °C to constant weight\[28\]. Total lipid was extracted from the muscle tissues using Bligh and Dyer\[27\] method. The lipid content was gravimetrically determined. Ash was determined gravimetrically in a muffle furnace by heating at 550 °C constant weight\[26\].

2.3.2. Fatty acids analysis

Fatty acid methyl esters (FAME) were prepared by methylation of the total lipids (TL), as described by Joseph and Ackman\[28\]. The fats were converted to free fatty acids by saponification. The fatty acids were converted to their methyl esters and into heptane. Internal standards were used for estimation of actual fatty acids present in the fat. Identification/quantification of fatty acids was achieved by gas chromatography, the former being resolved by elution times. Internal standards were used for estimation of actual fatty acids present in the fat. Identification/quantification of fatty acids was achieved by gas chromatography. The lipids were esterified and the fatty acid methyl esters were analyzed on a Thermo quest trace gas chromatograph equipped with SP–2330 fused silica capillary column, (30×0.25 mm ID 0.20 μ m film thickness. Column injector and detector temperatures were 240 and 250 °C, respectively. Carrier gas, helium; split ratio 1/150; column flow 75 ml/min; make–up 30 ml/min (He) range 1; sample injection 0.5 μ L. The fatty acid methyl mixture No. 189–19 was used for standards (Sigma). The fatty acids were calculated by percentage of total lipid.

2.3.3. Estimation of amino acids

The experimental lyophilized samples were finely ground for estimating the amino acids in the HPLC (Merck Hitachi L–7400) following the method of Baker and Han[7]. About 0.5 g sample was weighed into a 100 mL flat bottomed flask, 1 mL of Norleucine standard solution, 5 mL of performic acid in ice bath. The oxidation procedure was carried out in a fridge for 16 h after which 0.84 g of sodium metabisulphite, 30 mL 6N HCl and anti bumping granules were added. The mixture was hydrolysed for 24 h in PEG bath set at 130 ºC after which it was allowed to cool and 30 mL of 4 M lithium hydroxide added. The pH was adjusted to 2.1 and the mixture made up to 100 mL final volume. About 5 mL of the sample was filtered through 2 μm filter and this was run through a Biochrom 20 Amino Acid analyzer.

2.3.4. Estimation of vitamins and minerals

The samples were finely ground for estimating the vitamins and minerals. The samples were analyzed by Liquid chromatography by following the protocol British Pharmacopoeial[30].

2.3.5. Statistical analysis

Analysis of variance was used to evaluate the analysis data and data were expressed as Mean±SD. Statistical calculation was performed with SPSS 15.0 for windows.

3. Results

3.1. Proximate composition

The protein content in the THF was found to be 32.59% whereas in TBF the protein content was 31.50%. This result emphasizes that both the head and bone flours have more or less equal proportion of protein content. But the carbohydrate content of TBF was 1.45% low when compared with that of THF 0.2014%. The TBF also had low values of moisture and ash when compared with that of THF. The results are summarized in Table 1. Thus the tilapia head and bone flours have an important role as nutritional alternative due its high level of protein content.

2.3.4. Estimation of fats and lipids

The fatty acids in fishes are derived from two main sources namely bio-synthesis and diet[31]. The fatty acid composition as a percentage of eluted methyl esters of the two flours is summarized in Table 2. The sequence of the fatty acids is ordered according to their chromatographic retention times. The saturated fatty acids were found to be 3.16% in THF and 0.89% in TBF. The unsaturated fatty acids were found to be 1.96% in THF and 0.12% in TBF. The PUFA content was 2.55% in THF and 0.11% in TBF. The fatty acid composition of THF occurring in the highest proportions were alpha linolenic acid (C18: 3; 2.43%), stearic acid (C18: 0; 1.983%), linoleic acid (C18:2; 1.9860%), palmitic acid (C16: 0; 1.17%), oleic acid (C18:1; 1.54%) margaric acid (C17:0; 0.41%) and moroctic acid (C18:4; 0.11%). The fatty acid compositions of TBF occurring in the highest proportions were stearic acid (C18: 0; 0.7860%), oleic acid (C18:1; 0.114%), alpha linolenic acid (C18: 3; 0.1141%), palmitic acid (C16: 0; 0.1143%), linoleic acid (C18:2; 0.0816%), n-3 fatty acid (C17:0; 0.0088%) and moroctic acid (C18:4; 0.0034%). EPA, DHA and other fatty acids were was detected in very low amounts. The results were not significant in the statistical analysis (P < 0.05).

3.3. Amino acid content

Twenty different amino acids were obtained in the head and bone flours of tilapia (Oreochromis mossambicus). Nine essential amino acids that are very important for the human body are all present in the THF and TBF flours. These essential amino acids are lysine, leucine, valine, isoleucine, threonine, phenylalanine, histidine and tryptophan. The major amino acids such as glutamic acid (0.9967%), aspartic acid (1.837%), lysine (1.048%) and leucine (0.8981%) were found in THF and in TBF the major amino acids were found as glutamic acid (0.7865%), aspartic acid (0.9686%), lysine (1.342%) and leucine (0.775%). The amino acid composition of THF and TBF is listed in Table 3 and the retention peaks for the essential amino acids in THF and TBF is shown in Figure 1 and Figure 2.

4. Discussion

Amino acids are also important in healing processes and the composition of amino acids in fish is similar to that in man, people can acquire essential amino acids in abundance and proper balance by eating fish. The essential amino acids cannot be manufactured in human bodies, but can be obtained from food. The present study indicated that the two species had all the essential amino acids. Deficiency in the essential amino acids may hinder healing recovery process. Leucine promotes the healing of bones, skin and muscle tissue. Isoleucine is necessary for haemoglobin formation, stabilizing and regulating blood sugar and energy. Glycine, which is one of the major components of human skin collagen, together with other essential amino acids such as alanine form a polypeptide that will promote growth and tissue healing. Other reports of similar nature provided valuable information on selecting fish and fish oils for nutritional purposes.

The TBF and THF flours possessed seven essential minerals such as calcium, magnesium, zinc, iron, copper, sodium and potassium. Among the seven vitamins reported Vitamin A was predominant in THF which ranged as 145.6 mg/g and vitamin C was found higher in TBF which ranged as 45.65 mg/g. The TBF lacked vitamin K where as THF contained 0.8981mg/gm of vitamin K. The list of vitamins detected in the THF and TBF is listed in Table 4. Calcium was reported as the major mineral in both the head and bone flours. The minerals estimated are listed in table 5. The results indicate that vitamin A and C are dominant in both the flours.
