Abstract:
Aim: The study was designed to evaluate the Antidiabetic activity of ethanolic leaves extract of P. deltoides.
Method: The P. deltoides ethanolic leaves extract was tested for the presence of various phytoconstituents using standard procedure. The leaves extract was tested for its hypoglycaemic property in healthy albino rats and glucose loaded rats. The effect of extract was evaluated for its antidiabetic action in alloxan induced rats. The effect of extract on heart and kidney was determined by measuring biomarkers like total cholesterol, triglycerides, HDL, creatinine, BUN, CPK and protein in diabetic rats. The histopathology of pancreas was studied to support the experimental results.
Result: The P. deltoides ethanolic leaves extract revealed the presence of variety of chemical constituents like glycosides, tannins, amino acids, alkaloids, protein, flavanoids, terpenes, phenols, saponins. The P. deltoides leaves extract exhibited significant reduction in blood glucose level in healthy albino rats and overloaded glucose levels. The extract exhibited significant reduction in blood glucose level in alloxan induced diabetic rats. The percentage of reduction was highest at 500 mg/kg dose of ethanolic extract at 48.55% at 7th day of the treatment. The extract protected experimental animals against cardiotoxicity and nephrotoxicity in diabetic and normal animals.
Conclusion: The ethanolic extract of P. deltoides exhibited significant hypoglycaemic property in healthy and diabetic albino rats. The extract protected the diabetic albino rats against cardiac and nephrotoxicity.

Keywords: alloxan, cardioprotective, hypoglycemia, Populus deltoides.

Please cite this article in press as Rajeev Jha et al, Evaluation of Antidiabetic Activity of Leaves Extract of Populus Deltoides, Indo Am. J. P. Sci, 2017; 4(05).
INTRODUCTION: Natural compounds with Antidiabetic activity, in descending frequency of occurrence, include complex carbohydrates, alkaloids, glycopeptides, terpenoids, peptides and amines, steroids, flavonoids, lipids, coumarins, sulfur compounds, inorganic ions and others[1]. Plants have always been a good source of drugs. About 800 plants that may possess antidiabetic potential as reported by ethno botanical information[2-4]. The beneficial uses of medicinal plants in traditional system of medicine of many cultures are extensively documented.

P. deltoides is an Indian traditional medicinal plant containing flavanoids in leaves used in the therapy of rheumatism, gout, scurvy, blood purifier, anticancer and pain. It is also used in case of urinary problems, thinner of bronchial secretions and tonic as diuretic, uric acid eliminator, antiinfectious[5]. Recent studies on diabetes claims that the flavanoids have antidiabetic activity[6]. However the literature reveals no scientific data on antihyperglycemic effect of P. deltoides. Many of the plants having antioxidant properties have been proved to possess antidiabetic property[7]. Hence the current research work focuses on evaluating the antidiabetic potential of a P. deltoides leaves extract in alloxan induced diabetic rats.

METHODS:

Plant materials
The leaves of P. deltoides were collected from the garden of Dehradun, Uttarakhand. The leaf was identified and authenticated by Dr. K. Ravikumar, senior botanist at FRLHT (Foundation for Revitalisation of Local Health Traditions) Jarakabande Kaval, post Attur, Yelahanka, Bengaluru (560106). A herbarium specimen was preserved in the college museum for future reference. The leaves were shade dried at room temperature for 15 days and pulverized.

Animals
For pharmacological experiments, male albino rats (180-220 g) were used. Animals were acclimatized and were maintained under standard condition in an animal house approved by the Purpose of Control and Supervision of Experiments on Animals (CPCSEA). The study protocol was approved by the Institutional Animal Ethics Committee (IAEC), Liveon Biolabs Private Limited, Tumkur. Reg. no. 1432/PO/a/11/CPCSEA.

Effect of P. deltoides leaves extract on blood glucose level on normal albino rats
The experiment was carried out to find out the effect of P. deltoides leaves extract on blood glucose level on healthy albino rats.

Experimental procedure
The normoglycemic study was carried out in the same group of animals which were used in part I. In this study the treatment as part I was continued by administering respective doses to each group everyday for next 28 days. Animals were fed with normal diet and water. The blood samples were collected from tail tip on 0, 7th, 14th, 21st, 28th, day respectively and were analysed for fasting blood glucose level by using a commercial glucometer. The percentage reduction in blood glucose levels was calculated. The fasting blood glucose level and percentage reduction are expressed as mean ± SEM in the Table no. 5, and graphically represented in Fig no. 1.

Experimental procedure
Group-I - Normal control rats were treated with normal saline only.
Group-II - Received glipizide (5 mg/kg p.o.) standard reference drug.
Group III - Received ethanolic extract of P. deltoides (250 mg/kg p.o.).
Group IV - Received ethanolic extract P. deltoides (500 mg/kg p.o.).

Effect of P. deltoides leaves extract on blood glucose level on glucose overloaded in healthy albino rats
Oral glucose tolerance test was studied in glucose overloaded male albino rats weighing between 180-220 g. The animals were divided into four groups containing six animals each and marked conveniently. The animals were fasted overnight before commencing of the experiment. During this period, rats were allowed to take adequate water. The rats of group-I were treated with vehicle, group-II received glipizide (5 mg/kg p.o.), the remaining two groups were treated orally with 250 mg/kg and 500 mg/kg ethanolic leaves extracts respectively. After 30 min of the drug treatment, the animal of all the groups were fed with glucose (4 g/kg p.o.) and blood glucose level was determined after 0.5, 1, 2, and 4 hours of the glucose load. Blood glucose level was estimated by using a commercial glucometer and a data of % reduction of blood glucose was recorded and tabulated in table 6 and represented as the graph in fig. 2.

Evaluation of antidiabetic potential and secondary diabetic complications of plant extract of P. deltoides on alloxan induced diabetic rats
Preparation of diabetic rats
Male albino rats weighing between 180-220 grams were selected and fasted for 18 hours with water.
ad-libitum. The rats were administrated with alloxan monohydrate (120 mg/kg, p.o.) dissolved in normal saline (0.9% w/v of NaCl in distilled water) intraperitoneally. The rats were treated with 20% glucose solution intraperitoneally after 6 hours. They were kept for the next 24 hours on 5% glucose solution bottles in their cages to prevent hypoglycemia. The blood samples were collected after 24 hours by slicing tip of the tail and blood glucose levels were determined by using a commercial digital glucometer. Rats with blood sugar levels more than 300 mg/dl were considered to be diabetic. Animals were allowed to stabilize for 4 days and further employed in the study. The mortality rate of the rats after alloxan treatment was found to be 25%.

Experimental procedure
Thirty male diabetic albino rats weighing between 180-220 grams were selected and divided into 5 groups containing six animals each and marked conveniently. The animals were fasted for 18 hours before commencing the experiment. During this period, the rats were allowed to take adequate water. The fasting was continued till the completion of the experiment. Group-I: Normal control rats were treated with normal saline only. Group-II: Diabetic control rats alloxanized (120 mg/kg, B. W.) received only vehicle. Group-III: Received glipizide (5 mg/kg, p.o.) standard reference drug. Group IV: Received ethanolic extract of P. deltoides (250 mg/kg, p.o.). Group V: Received ethanolic extract P. deltoides (500 mg/kg, p.o.)

The experiment was continued by administering the fixed dose of treatment everyday for 28 days. Blood glucose was estimated by withdrawing blood samples from tail tip at 0, 7th, 14th, 21st and 28th of treatment. The data was recorded and percentage reduction of blood glucose level was calculated and noted in table 7 and graphically shown in Fig. 3. The body weight, food and fluid intake of all groups of animals was monitored on a daily basis for 28 days at regular time. Fixed amount of rat chow and fluid were given to each rat and replenished the next day.

At the end of 28th day, blood sample was withdrawn from retro orbital plexus into fresh centrifuge tubes and centrifuged at 3000 rpm for 10 min to obtain serum and plasma. Serum samples were stored at 4°C until utilized for further biochemical estimation parameters such as total cholesterol, total triglycerides, HDL, Creatinine, BUN, CPK Total, protein. The animals were sacrificed by cervical dislocation and the organ like pancreas was collected for histopathological investigation.

BIOCHEMICAL ESTIMATION:
The serum was stored at 4°C for the estimation of Total cholesterol, triglyceride, HDL, Creatinine, BUN, CPK TOTAL and protein. The estimations were performed using the standard procedures.

a) Estimation of serum Total Cholesterol-TC8

(CHOD-PAP: enzymatic photometric test)

Principle:
Determination of cholesterol after enzymatic hydrolysis and oxidation. The colorimetric indicator is quinoneimine which is generated from 4- aminoantipyrine and phenol by hydrogen peroxide under the catalytic action of peroxidase (Trinder’s reaction).

Cholesterol ester + H2O \[\text{CHE}\] Cholesterol + Fatty acid

2H2O2 + 4- Aminoantipyriene + Phenol \[\text{POD}\] Quinoneimine + 4 H2O

Table 1: Reagents used for the estimation of serum Total Cholesterol

| Good buffer | pH 6.7 | 50 mmol/L |
| Phenol | 5 mmol/L |
| 4-Aminoantipyrine | 0.3 mmol/L |
| Cholesterol esterase \((\text{CHE})\) | \(\geq200\) U/L |
| Cholesterol oxidase \((\text{CHO})\) | \(\geq50\) U/L |
| Peroxidase \((\text{POD})\) | \(\geq3k\) U/L |

Standard: 200 mg/dl (5.2 mmol/L)

Procedure:
Pipetted out 1000µL reagent and 10µL sample or standard or blank, it was mixed and incubated at 20-25°C for 20minutes or 10 minutes at 37°C. The absorbance was recorded at 500nm within 60 minutes against reagent, blank.

Calculation
Cholesterol \([\text{mg/dl}] = A \text{Sample/ A Std} \times \text{Conc. Std} \ [\text{mg/dl}]

Conversion factor:
Cholesterol \([\text{mg/dl}] \times 0.02586 = \text{Cholesterol} [\text{mmol/L}]

b) Estimation of serum of triglycerides[8]
Span diagnostic kit was used for estimation of triglycerides, which followed end point colorimetry enzymatic test using glycerol-3-phosphate oxidase.

Principle: The enzyme, lipoprotein lipase catalyzes hydrolysis of TGs to glycerol and FAs. Glycerol then is phosphorylated in an ATP- requiring reaction catalyzed by glycerophosphate. The formed glycerophosphate is oxidized to
dihydroxyacetone and H₂O₂ in a glycerophosphate oxidase catalyzed reaction. H₂O₂ then reacts with 4 -AAP and 4 - chlorophenol under the catalytic influence of peroxidase to form coloured quinoneimine complex, the intensity of which was measured at 505nm.

**Assay and Procedure:** Fresh clear and dehaemolysed serum was used for the estimation. The reaction mixtures were mixed well and incubated for 10 min at 37°C. The absorbance of sample and standard were measured against reagent blank at 505 nm. The absorbance was measured by using a Shimadzu spectrophotometer (model 1601).

c) Estimation of serum high-density lipoprotein cholesterol (HDL-C):
Span diagnostic kit was used for estimation of HDL cholesterol, which followed Cholesterol oxidase / peroxidase (CHOD-POD) method.

**Principle:** HDL-C is measured in the supernatant after the precipitation of the lipoproteins including chylomicrons, very low-density lipoproteins, low-density lipoproteins, intermediate-density lipoproteins directly from serum poly anions like phosphotungstic acid and along with MgCl₂ are added to an aliquot of serum an immediate heavy precipitation is formed. The precipitate then is sedimetted by centrifugation and HDL cholesterol is measured in the clear supernatant, which is estimated by enzymatic method as described earlier in estimation serum of TC.

**Assay & Procedure:** Fresh clear and unhaemolysed serum was used for the estimation.

**Standard:** The concentration of standard glucose used was 50 mg/dl.

**Reaction parameters:**

| Table 2: Reagents used for estimation of HDL-C |
|-----------------|-----------------|
| 1 | Reaction type | End point |
| 2 | Wavelength | 505 nm |
| 3 | Optical path | 1 cm |
| 4 | Temperature | 37°C |
| 5 | Measurement | Against reagent blank |

**Standard of assay details:**
1. 0.5ml of serum was taken into test tube and 0.5ml of precipitating reagent was added, mixed well and kept at room temperature for 15min.
2. Centrifuged for 15 min at 4000 rpm.

3. The clear supernatant was separated and immediately used to determine the cholesterol content as follows:

<table>
<thead>
<tr>
<th>Pipetted in to test tube</th>

</tr>
</tbody>
</table>

The reaction mixtures were mixed well and incubated for 10 min at 37°C. The absorbance of test and standards was measured against the reagent blank at 505 nm. The absorbance was measured by using a Shimadzu spectro photometer (model 1601).

d) Blood urea nitrogen[9]

**Principle:** Urea is hydrolysed in presence of urease to produce ammonia and CO₂ the ammonia produced combines with α-oxoglutarate and NADH in presence of GLDH to yield glutamate and NAD⁺.

\[
\text{Urea} + 2\text{H}_2\text{O} \rightarrow 2\text{NH}_4^+ + \text{CO}_2^2- \\
\text{NH}_4^+ + \alpha-\text{oxoglutarate} + \text{NADH} \xrightarrow{\text{MDH}} \text{L-glutamate} + \text{NAD}^+ + \text{H}_2\text{O}
\]

**Procedure:** Pipetted 1.0 ml of reagent into test tubes and allow reagent to attain 37°C. Added 0.01ml (10ul) of sample to test tube and immediately placed in the spectrophotometer. After thirty seconds absorbance was recorded. Sixty seconds after the first reading another reading was taken. The absorbance was recorded at 340 nm.

**Calculation:** Urea (mg/dl) = Abs. of test / Abs. of Std. X Conc. of Std.

e) Estimation of Creatine phospokinase (CPK)[10]

Creatine phosphorylase (CPK) activity is greatest in striated muscle, heart tissue, and brain. The determination of CPK activity is a proven tool in the investigation of skeletal muscle disease (muscular dystrophy) and is also useful in the diagnosis of myocardial infarction (MI) and cerebrovascular accidents. Increased levels of CPK also can be found in viral myositis, polymyositis, and hypothyroidism. Following injury to the myocardium, such as occurs in acute MI, CK is released from the damaged myocardial cells.

**Reaction:**

\[
\text{Creatine phosphate} \xrightarrow{\text{CPK}} \text{ADP} \\
\text{Creatine} + \text{ATP}
\]
**Procedure:** CK-MB activity in perfusate was estimated by using Kit method (Immuno inhibition method, Kinetic assay). The procedure involves the measurement of CK activity in the presence of an antibody to the CK-M monomer. This antibody completely inhibits the activity of CK-MM and half of the activity of CK-MB while not affecting the B subunit activity of CK-MB and CK-BB.

To 500 μl of working reagent solution, 25 μl of Anti CK-MM reagent (CK-MB LabKit, Span diagnostics) was added and mixed properly. 50 μl of perfusate was added and mixed on a vortex mixer and aspirated immediately into Semi-Auto Analyzer (ARTOS) at 37°C and 600 seconds delay time. Increase in absorbance was measured at 340 nm every minute starting from 0 minute up to 3 minute and change in absorbance was calculated.

**Calculations:** Using the protein standard solution a five point standard curve was prepared by performing serial dilutions between a range of 0-150 mg/mL. Used these with the biuret reagent to quantify serum protein for the blood samples from incremental exercise to fatigue.

**Calculation:**

\[
\text{CK-MB Activity} = \frac{\Delta E}{340 \text{ nm} \times 3697.75} \text{ (Kinetic factor) units/L, Where, } \Delta E/340 \text{ nm } = \text{ average change in absorbance at 340 nm}
\]

**f) Estimation of Serum protein[11,12]**

**Principle:** Biuret method was used for the estimation of serum protein. The principle of biuret method is a colorimetric procedure. The biuret reagent is based on a reaction between copper and molecules with at least 2 peptide bonds. The color intensity caused by this reaction is directly proportional to the number of peptide bonds, and therefore the amount of protein.

**Table 3: Reagents: Preparation of biuret reagent.**

</tr>
</tbody>
</table>

**Procedure:** Pipetted out 3 ml of Biuret reagent to an appropriate number of 12 x 75 mm glass tubes. Pipetted 50 ml of each sample from your serial dilutions, from the incremental exercise samples, and for distilled water (blanks) into the tubes. Incubated the tubes at room temperature for 30 min. During incubation, turned on and warmed-up the spectrophotometer. Prepared to run all samples at 540 nm, and recorded the absorbance values for the standards and unknowns. Calculated the serum protein concentrations using the regression equation from standard curve.

**HISTOPATHOLOGICAL STUDIES[13]**

The animals were sacrificed and their pancreas were isolated. The isolated pancreas was cut into small pieces and preserved in 10% formalin for two days. Then the pancreas pieces were washed in running water for about 12 hours. This was followed by dehydration with isopropyl alcohol of increasing strength (70%, 80% and 90%) for 12 hours each and the final dehydration was done using absolute alcohol with about three changes for 12 hours each. Clearing was done by using chloroform with two changes for 15 to 20 minutes each. After clearing the organ pieces were subjected to paraffin infiltration in automatic tissue processing unit. After processing tissue were embedded in paraffin wax. Sections were cut at 5µ thickness and stained with hematoxyline-Eosin for histochemical studies. After completion of staining sections were observed under microscope for histological change.

**RESULTS:**

The preliminary phytochemical study of 70% ethanolic extract of leaves of *P. deltoides* shows the presence of Alkaloids, saponins, flavanoids, phenolics, terpinoids, glycosides, proteins, amino acids and tannins.

Phytochemical Analysis
The 70% ethanolic extract of *P. deltoides* was subjected to qualitative test to identify the presence of phytoconstituents. The result of phytochemical analysis confirmed the presence of amino acids, glycosides, flavanoids, protein, alkaloids, phenols, terpenoid, tannin and saponins. The extract did not contain carbohydrates.
Acute toxicity study
The 50% of animals died at the dose of 5000 mg/kg p.o. therefore 1/10th and 1/20th of this dose are taken as higher and lower dose respectively. The results of acute toxicity study are summarized in table 4.

Effect of P. deltoides leaves extract on normoglycemic rats (NG).
On observation of data in the table 5 and figure 1, the results for the evaluation of P. deltoides extract on normal blood glucose revealed that, the animals in the normal group maintained around 95% mg/dl of blood glucose. The Glipizide 5 mg/kg p.o. reduced the blood glucose level significantly to 50, 49.5, 49 and 48.33 mg/dl on 7th, 14th, 21st and 28th day respectively. The P. deltoides ethanolic extract at 250 mg/kg, p.o. reduced the blood glucose level significantly on 7th, 14th, 21st, and 28th day of treatment. The P. deltoides ethanolic extract at 500 mg/kg p.o. also reduced the blood glucose significantly on all the tested days. The percentage reduction was at its peak on 28th day. The overall percentage of blood glucose reduction observed by P. deltoides ethanolic extract 500 mg/kg p.o. was found to be better in comparison with P. deltoides ethanolic extract 250 mg/kg, p.o.

Effect of P. deltoides leaves extract on blood glucose level of glucose overloaded healthy albino rats.
The results of OGTT are summarized in table 6 and figure 2. The standard drug glipizide 5 mg/kg, p.o. reduced blood glucose level 30.43% at 2nd hr and 46.02% at 4th hr. The ethanolic extract of P. deltoides 250 mg/kg, p.o. also reduced the blood glucose from 0.5th to 4th hour of treatment the highest being 11.36% at 4th hour. The ethanolic extract of P. deltoides at 500 mg/kg reduced the blood glucose from 0.5th hour to 4th hour and 19.14% was highest reduction observed at 4th hour.

Effect of P. deltoides leaves extract on alloxan Induced Diabetic rats.
a) Blood sugar level
The P. deltoides ethanolic extract at 500 mg/kg exhibited significant reduction of blood glucose level from 7th day to 28th day of the treatment 72.73% of reduction was found to be the highest and was shown on 28th day with 500 mg/kg of ethanolic extract. The ethanolic extract at the dose of 250 mg/kg also significantly reduced the blood glucose level in diabetic rats. The percentage of reduction was highest at 66.72% on 28th day. As compared to 500 mg/kg of ethanolic extract 250 mg/kg of ethanolic extract of P. deltoides showed nearly 6% less. And the results are presented in table 7 and figure 3.
b) Biochemical parameters in alloxan induced diabetic rat.
The results of P. deltoides ethanolic extract on biochemical parameters in alloxan induced diabetic rats are presented in Table 8 and Figure 4. The alloxan induced diabetic rats showed a hypercholesterolemia, hypertriglyceridemia and increase in levels of HDL, protein, CPK, creatinine and BUN levels when it is compared with the normal control rats to 70.33 mg/dl, 95.66 mg/dl, 61.5 mg/dl, 7 g/dl, 1335.33 IU/L, 0.7 mg/dl and 71.5 mg/dl.

Treatment with P. deltoides ethanolic extract at the dose 500 mg/kg p.o. showed decrease in total cholesterol, triglyceride, HDL, protein, CPK, creatinine and BUN to 51.33 mg/dl, 39.33 mg/dl, 47.33 mg/dl, 6.3 g/dl, 819.66 IU/L, 0.6 mg/dl and 40.33 mg/dl levels respectively which showed the data closer to the normal readings. P. deltoides ethanolic extract at the dose of 250 mg/kg p.o. also reduced the levels of same biomarkers to 60.33 mg/dl, 74 mg/dl, 31.33 mg/dl, 6.5 g/dl, 851.66 IU/L, 0.633 mg/dl and 68.33 mg/dl as compared to diabetic control.

c) Histopathological investigation
The pancreas of albino rats of control group showed normal histology and appearance of Islet of Langerhans containing α, β and δ cells. The β-cells are the most abundant cells (Figure 5 a). Pancreas of diabetic rats showed reduction in number of β cell and necrosis along with few surviving β-cells. Severe infiltration of inflammatory cells was also observed. It showed marked degeneration of the Islet of Langerhans and it also shows the fat deposition (Figure 5 b).

In the reference group, i.e., diabetic rats treated with glipizide, pancreas architecture was similar to that observed in control rat and it also showed slight regeneration of the beta cell, less damage to beta cells as compared with the diabetic rat (Figure 5 c).

The pancreas of the rats treated with the ethanolic extract of P. deltoides at the dose of 250 mg/kg p.o. showed reduction in the extent of necrosis, inflammation, increased in the number of islet cells of pancreas and less deposition of the fatty material as compared with the diabetic control (Figure 5 d). Histopathological study of pancreas of diabetic rats treated with alcoholic extract of P. deltoides at the dose of 500 mg/kg p.o. body weight showed a significant improvement in number of β-cells with the diabetic rats. It was observed that it exhibited less damage to beta cells, improved beta cell regeneration and shows slight necrosis as compared to diabetic rat (Figure 5 e).

DISCUSSION:
The ethanolic leaves extract of P. deltoides were evaluated for its hypoglycaemic effect in healthy rats and alloxan induced diabetes in albino rats. The P. deltoides ethanolic extract significantly reduced the blood glucose in normal healthy rats.
The ethanolic extract of *P. deltoides* also reduced the blood glucose in glucose overloaded in healthy albino rats. This effect may be due to reduction of glucose absorption or due to increased insulin secretion. The effect on blood glucose was evaluated on alloxan induced diabetic rats, to record its action in pathophysiological condition. The ethanolic leaves extract of *P. deltoides* at 500 mg/kg dose significantly reduced blood glucose levels in diabetic rats. The extract at the dose of 250 and 500 mg/kg reduced 66.72 and 72.73% of blood glucose respectively on 28th day of treatment. The results of histopathological studies revealed that the *P. deltoides* 250 mg/kg and *P. deltoides* 500 mg/kg have increased the number of β-cells and also decrease necrosis and inflammation in the pancreas. The antidiabetic activity of ethanolic leaves extract of *P. deltoides* may be due to reduction of necrosis and regeneration of β-cells leading to increase insulin release. Flavanoids might cause regeneration of β-cells. The antioxidant property of phenolic glycosides found in *P. deltoides* has already reported. Antioxidant property of *Populus species* may also play a role in its antidiabetic property. The lipids profile, BUN, creatinine, CPK and protein were also reduced but statistically not significant compared to standard glipizide. Antidiabetic activity of *P. deltoides* might be due to the presence of glycosides, flavanoids but exact molecular mechanism by which it produced the hypoglycemic activity could not be drawn from the present study. Further study has to be conducted to know the molecular mechanism of the extract.
