Objectives: The objective of this study was to determine the cholelithiasis surgical incidence in Multan and its adjacent areas.

Design: The design of the study was cross-sectional.

Settings: Research was conducted at various surgical units of Nishtar Hospital Multan, Fauji Foundation Hospital, Wapda Hospital, Railway Hospital Multan, Zubaida Fatima Memorial Hospital.

Patients: The study included a total of 2035 patients (483 males and 1583 females) aged 10–80 years who underwent gallstone surgery from January 2015 to December 2017.

Measurements: Cholelithiasis surgical incidence in the time span of January 2015 to December 2017 was the focus of this study. We used a questionnaire to study the said incidence and noticed the age, sex, dietary habits, gallstone presentation month in the patients.

Results: Gallstone incidence was observed in males and females respectively 4.0% and 14.2%, the proportion of male to female was one to 3.3. Peak months were the months of May and November in which number of cases were observed with the gallstone presentation. Males were in the age group of 10–78 years; whereas, females were in the age group of 11–80 years. Male and female peak age for the incidence of gallstone was respectively 45–59 years and 30–44 years. More prone ages for gallstone were observed in females and males respectively as 30 years and 44 years in comparison to other age groups.

Conclusions: An overall cholelithiasis surgical incidence was observed as 9.03% (95% Confidence interval, 8.6% - 9.4%), the incidence was more in females observed 3.3 times higher than the males in the incidence of gallstones development.

Key Words: Cholelithiasis, surgical incidence and gallstones.

INTRODUCTION:
Cholelithiasis is one of the major healthcare issues among numerous countries specially in the developed countries. Adults are commonly involved in this healthcare issue of gallstones more than elderly and children, it is common in females more than males. Well known causes include sex and age-related variations. Gallstone incidence have been tried to established in many countries through epidemiological research studies [1]. We included the statistical data of five main hospitals of Punjab and tried to establish the incidence of cholelithiasis from 2015 – 2017. We also compared our outcomes with the findings of other countries and observed differences and similarities.

Analysis
Research analyzed that the cases of gallstones were observed in all the cholecystectomy cases, same has already been observed through USG assessment. Standard Jack knife technique was used for the measurement of the surgical incidence (CI as 95%).

RESULTS:
As shown in Table – I, research studies the cholelithiasis surgical incidence in the 5 hospitals of Multan in the time period as mentioned earlier with CI as 95 percent. The names of the hospitals are also mentioned earlier where the research was carried out. These hospitals are charitable, government and private hospitals. We observed a highest surgical incidence of 13.1 percent with CI as 95 percent (CI, 12.2 – 14.08). Low social status cases were treated in Wapda hospital with the respective values of Relative Risk and CI as 2.49 & 95% (2.1 – 2.5), these patients were also observed with the consumption of rapeseed oil. Various surgeries carried out in the settings of various hospitals are also reflected in this research during this research. We can observe that an overall cholelithiasis surgical incidence was observed as 9.03% with CI (8.6 – 9.4). Male and female had the respective surgical incidence of 4.0% males CI (3.6% – 4.5%) and 14.2% females CI (14.1% – 15.7%).

Figure – II represents the month-wise gallstone presentation. Peak months were observed as the month of May and November for the cases of gallstone in this research. Sex and age-wise distribution has been shown in Table – II for the incidence of gallstone. More prone were the females in the age limit of 30 – 44 years with the other involved age groups in the incidence of gallstone.

We observed that in the research time period gallstone surgical incidence specially in females increased step by step and a decrease was observed in the males as shown in Figure – III.

Figure 1: Statistics of patients surgically treated in different hospitals of Multan during Jan. 2015 to Dec. 2017.

Figure 2: Month-wise presentation of gallstone cases indifferent hospitals of Multan during 2015 to 2017.
DISCUSSION:
It is obvious from the all available literature supported reports that female dominance was observed in the cholelithiasis surgical incidence [2]. Our research observed that cholelithiasis surgical incidence in male and female was respectively 4.0% & 14.2% as these cases were treated at various healthcare facilities of Punjab which is comparatively far below than the Netherland outcomes; in Netherland the same incidence in males and females was observed respectively 39% & 50% irrespective of age group [3]. A number of gallstone cases in the target area were managed in the expectant manner. Moreover, it is another possibility that number of other cases also have gallstone disease asymptomatic in nature [4].
The surgical incidence may be attributed to these reasons for the gallstone disease prevalence observed in the target populations. It was seen that the gallstone incidence was 9.2% as observed in an Italian research and respectively for other countries like the incidence of gallstone was observed in Spain [5], Chile and Thailand as 9.7%, 28.5% and 3.1% [6]. The sun effect in the shape of ultraviolet rays or their exposure is also implicated in cholesterol gallstones pathogenesis. The highest incidence prevalence was also observed in the hot and humid season that may also be attributed a reason of gallstone incidence as the exposure to sun is increased in these months [7]. Moreover, our previous observations about the cholesterol gallstones are common in this region as (77.9%), which support and strengthens this argument of cholesterol gallstones pathogenesis in the target populations in specific and humans in general [8].

![Figure 3: Sex-wise cholelithiasis surgical incidence in 5 various Multan hospitals during 2015 – 2017.](image)

The reason may be an ill routine of diet in the long summer season in the target population. Detailed investigative research is required to probe this point in detail [11].
In the outcomes of this research it can be seen that male and female both were hospitalized for the gallstone incidence, this incidence was less prevalent in at the age of fourteen years, it also increased as the age increased. Females were dominant in the incidence of gallstone over males. Peak age limit in female and male was observed as (30 – 44 year) and (45 – 59), respectively [12]. It gradually decreased in the male population of this research. The variations in the male to female was observed in terms of proportion as (1 to 4.6) at the range of age as (30 – 44 years) [13]. We can associate this difference which is related to sex as hormonal change in the women during pregnancy, since during pregnancy and hormonal increase normal level of blood cholesterol is observed just after parturition and within or during menstrual period [14]. Our ratio of male to female was (1: 3.3), which is different from the ratios of Mexican Americans and Pima Indians respectively (1:5.3) & (1:16.6) [15].
The increase which was seen female gallstones surgical incidence during the research period as shown in Figure – III requires more authentic oral contraceptives reports. However, an increase in the cases of gallstone surgical incidence of the female population can be associated to the enhanced educational and awareness levels in the general population about innocuous gallstone surgical treatment.

CONCLUSIONS:
An overall cholelithiasis surgical incidence was observed as 9.03% (95% Confidence interval, 8.6. 9.4), the incidence was more in females observed 3.3 times higher than the males in the incidence of gallstones development.
