Abstract:
Objective: To determine the frequency of stroke associated pneumonia in stroke patients. Methodology: A total of 100 diagnosed stroke cases between 30-70 years of age of either gender were included in the study from July 2017 to December 2017 during six months. We excluded those cases with a history of pneumonia. We performed a complete examination and history of the patients was obtained. All diagnosed cases of stroke were followed till 30 days (either in medical ward/outdoor) for stroke associated pneumonia, with positive finding in chest X-ray and culture of tracheal aspiration.

Results: Patients were distributed according to age, which shows that 21.05%(n=60) were between 30-50 years of age while 78.95%(n=225) were between 51-70 years of age, mean+sd was calculated as 56.86+6.81 years, 51.58%(n=147) were male and 48.42%(n=138) were females. Frequency of stroke associated pneumonia in patients with stroke was recorded in 17.89%(n=51) while 82.11%(n=234) had no findings of the morbidity.

Conclusion: We concluded that the frequency of stroke associated pneumonia is quite high among stroke patients. However, these cases should be diagnosed early managed accordingly.

Key Words: Acute ischemic stroke, stroke associated pneumonia (SAP), association

INTRODUCTION:
Stroke is a major cause of morbidity and mortality [1,2]. A recent community-based survey suggested an estimated 21.8% prevalence of stroke and/or Transient Ischemic Attack in Pakistan [3]. Stroke-specific fatality recorded between 7 to 20% in multiple studies conducted at Pakistan. Approximately 63% of all stroke patients develop complications and up to 89% are dependent for activities of daily living. The risk factors for stroke are similar to the Western population and mostly comprise of hypertension, smoking, dyslipidemia, cardiac disease and Diabetes [4,5].

Medical and neurological complications, including pneumonia, are found to be major causes of death after stroke [6]. The incidence of stroke-related pneumonia appears to be significantly higher in those cases having acute ischemic stroke admitted for treatment to a neurologic ICU and those who require nasogastric tube feeding (21% and 44%, respectively). Pneumonia is the most common cause of fever within the first 48 hours of acute stroke, and it is the most common medical complication two to four weeks after a supratentorial ischemic infarction [7].

This study was planned with the view that in our population recent findings are not recorded and no research data is available, the recorded magnitude in previous literature is not consistent which needs another recent study to record and compare with other studies so that the recent research-based statistics may be determined to for this issue.

MATERIAL AND METHODS:
A total of 100 diagnosed stroke cases between 30-70 years of age of either gender were included in the study from July 2017 to December 2017 during six months. We excluded those cases with a history of pneumonia. We performed a complete examination and history of the patients was obtained. All diagnosed cases of stroke were followed till 30 days (either in medical ward/outdoor) for stroke associated pneumonia, with positive finding in chest X-ray and culture of tracheal aspiration.

RESULTS:
A total of 100 cases fulfilling the inclusion/exclusion criteria were enrolled to frequency of stroke associated pneumonia in stroke patients.

Patients were distributed according to age, which shows that 21.05%(n=60) were between 30-50 years of age while 78.95%(n=225) were between 51-70 years of age, mean+sd was calculated as 56.86+6.81 years. (Table No. 1)

Patients were distributed according to gender, it shows that 51.58%(n=147) were male and 48.42%(n=138) were females. (Figure)

Frequency of stroke associated pneumonia in patients with stroke was recorded in 17.89%(n=51) while 82.11%(n=234) had no findings of the morbidity. (Table No. 2)

DISCUSSION:
Stroke-associated pneumonia (SAP) is associated with the morbidity, mortality and an elevated medical cost in patients suffering with acute ischemic stroke. Previously, the rate and prognosis of stroke-associated pneumonia has not been ruled out thoroughly in our country. However, we planned this study to record the rate of SAP.

We recorded mean age as 54.16±7.22 years, 51%(n=51) male and 49%(n=49) females, frequency of stroke associated pneumonia in patients with...
stroke was recorded in 17.89%(n=51). We compared our results with Chamorro A et al who recorded pneumonia may occur in 7-22% of stroke patients. Another study by Finlayson Orec that Stroke-associated pneumonia was observed in 587 patients (7.1%).

Another recent study recorded the incidences of SAP in the following settings NICUs 4.1-56.6%, MICUs 17-50%, stroke units 3.9-44%, mixed studies 3.9-23.8% and rehabilitation 3.2-11%. However, or findings are closely in agreement with the above studies.

The rate of SAP among the most of the studies based on NICU ranged between 9.5% to 56.6% except a study where it was recorded as 41.1. However, this study included all types of neurovascular cases in addition to stroke patients and younger in age. The rate was higher among febrile cases (40.2-70.8%) showing the importance of SAP as a risk factor of fever after stroke. The MICU studies reveal these findings in 17 and 50% and seemed to be similar to the studies conducted at NICU. Various SAP studies are performed in stroke units or in mixed acute settings. The rate of SAP among most of the studies performed exclusively in stroke units varies between 3.9 and 12% except a study where it was recorded in 44% of the cases. It may reflect biasness in selection as enrolled in the study had nasogastric tube feeding, the rate of mechanical ventilation was higher as (18%) and the severity level of stroke was more severe. Some other trials performed in mixed acute settings recorded an incidence between 3.9% to 23.8%, whereas the incidence among selected rehabilitation trials ranging from 3.2 to 11% cases.

It is really hard to compare these studies with the fact that they are highly heterogeneous; particularly those studies conducted in critical care settings. Most of the ICU studies enrolled intracerebral or subarachnoid hemorrhage in addition to AIS. Few of them included AIS alone, while the majority of them were performed in acute general floors or stroke units. There may also be differences in definition of SAP, the incidence of mechanically ventilated cases may also vary. The rate of SAP was recorded to be similar in MICUs and NICUs and higher than those at the stroke units or acute general floors.

In summary, we are of the view that the frequency of stroke associated pneumonia in stroke patients revealed in our study is comparable with other studies. However, some-other studies are required to validate our findings.

CONCLUSION:
- We concluded that the frequency of stroke associated pneumonia is quite high among stroke patients. However, these cases should be diagnosed early managed accordingly.
