The disappearance of atrial tachycardia paroxysms after radiofrequency catheter ablation (RFA) of ectopic focus in a left atrium is presented on example of clinical case. Atrial tachycardia paroxysms disappeared after ablation completely.

KEY WORDS: atrial tachycardia paroxysms, radiofrequency catheter ablation

INTRODUCTION

Atrial tachycardia accounts for approximately 20% of all supraventricular tachycardia [1]. Heart ablation is based on duplication or destruction of those tissues that provoke an irregular heartbeat [1–3]. Heart ablation is the most effective method of treatment, if the previous pharmacotherapy was not effective or it cannot be used due to side effects in the body [1–4].

Taking this into account, we present a clinical case that demonstrates the disappearance of atrial tachycardia paroxysms after radiofrequency catheter ablation (RFA).

CLINICAL CASE

54 years old woman, a resident of Donetsk region. Diagnosis during hospitalization: Permanent-recurring atrial tachycardia.

Complaints: shortness of breath, palpitation, diffuse headaches in a high blood pressure periods, dizziness, general weakness.
Anamnesis morbi: patient suffers from hypertension for about 10 years (maximal blood pressure \( BP = 160/90 \) mm Hg). During the same time, heartbeat attacks, provoked by stress, nearly 1 time in 6 months, initially stopped independently during rest. Last 2 years heartbeat attacks became more frequent (every 3 months), which were stopped by anti-arrhythmic drugs. On electrocardiogram (ECG) a supraventricular tachycardia with narrow QRS complexes, with rate of 140–160 per minute, \( P \) is not differentiated.

Medicinal therapy (regular cardiomagnil, irregularly bisoprolol) without effect. RFA intervention is recommended. Anamnesis vita: carried diseases: angina in childhood, occasionally catarrhal diseases. Family history: patient notes hypertension and atrial fibrillation in her mother. She denies harmful habits. Tuberculosis, viral hepatitis, diabetes mellitus, sexually transmitted diseases, transfusion therapy is not heeded, heart rate \( 150 \) per min, vertical position of electrical heart axis, left ventricular (LV) hypertrophy. Holter monitoring (January 31, 2017): aorta and valves closure, mitral valve regurgitation of 1 degree, heart chambers are not dilated. The LV walls are not thickened. The LV systolic function satisfactory during severe tachycardia. Zones of local contractility violations are not localized. Right chambers are not dilated. Tricuspid regurgitation of 1 degree, ejection fraction (EF) – 61 %. Heart rate variability (HRV) was recorded at sinus rhythm before RFA \( (01.02.2017) \), it reflected the high total power (TP) of spectrum, and after RFA TP decreased by 5 times, but remains high, it indicating a slow humoral and metabolic type of regulation.

02.01.2017 RFA was performed – complete isolation of ectopic zone in the left atrium was performed. Clinical diagnosis: coronary artery disease: diffuse cardiосclerosis. Atrial recurrent tachycardia with successful ablation, with the disappearance of tachycardia paroxysms and restoration of cardiac rhythm. Arterial hypertension II st. 1 degree, cardiovascular risk is low. Heart failure I st., I functional class (FC) with preserved systolic function of LV. Our recommendations: cardiologist observation at the place of residence. Bisoprolol 5 mg per day, in the morning, under the control of heart rate. Cardiomagnil 75 mg per day, before sleeping for a long time. Phone visit \( (02.03.17) \): patient lives at the far distance from our center, which makes it impossible for her physical visit. A month later, after an RFA, patient reported heart rhythm disturbances, which were twice a month, lasted about 15-20 minutes and stopped at rest. The patient takes bisoprolol 5 mg/day and cardiomagnil 75 mg/day. Epilogue: at the moment when the article was completed, during the second telephone visit \( (04.04.17) \), patient did not mention disturbances of heart rhythm. Patient was advised to take bisoprolol 10 mg/day. It is noted in literature that in acute postablative period there are possible rhythm disturbances with future recovery [5–6].

**CONCLUSIONS**

In this case, the RFA of atrial tachycardia was effective. The initial high total power of the HRV spectrum in the patient after ablation
decreased by 5 times, but may predict rhythm disturbances in future. In pharmacotherapy, which included cardiomagnil and bisoprolol, the reduction in HRV suggested a gradual increase of the bisoprolol dose.
