Abstract

Introduction: Space occupying large abdomino-pelvic ovarian tumours are uncommon. Such huge ovarian tumours in postmenopausal women have to be evaluated as they raise the suspicion of malignancy. The prevalence of ovarian neoplasm in postmenopausal women is 14-18% with a risk of 10-40% in the case of large complex ovarian cysts.

Objective: To study the clinical features, imaging and management of 5 post-menopausal women with large benign ovarian tumours.

Materials and Methods: A retrospective study in a tertiary care institutional hospital between December 2017-February 2018 among 5 post-menopausal women with large benign ovarian tumours.

Results: All of them presented with abdominal distension, abdominal pain and breathing difficulties. They underwent exploratory laparotomy with frozen section. Histopathology reports of all 5 showed benign ovarian tumours, the most common being serous cystadenoma.

Conclusion: The large size of the ovarian tumour warrants surgical removal of the same. This case series shows that not all extremely large tumours need to be malignant. Patients also present at a much later stage due to lack of awareness, ignorance and logistic reasons.

Keywords: Large benign ovarian tumours, Post-menopausal women.

Introduction

Ovarian cancers are the second most common gynaecological neoplasm and the seventh most common cause of cancer deaths worldwide. Menopause increases the likelihood of developing ovarian tumours. The chances of ovarian cysts in post-menopausal women being malignant is around 14% - 18%. In case of ovarian cysts of size less than 5 cm, risk of malignancy is only 0-1%. However, in the case of large complex cysts, the risk is 10%-40%. The most common benign ovarian tumour in post-menopausal woman is serous cystadenoma.

Objective

To study the clinical features, imaging and management of large abdomino-pelvic ovarian tumours in post-menopausal women.

Results

The findings of this case series are illustrated in Table 1. The mean age of presentation of symptoms was 54.6 years. Average number of years after menopause, at which the abdominal mass was diagnosed was 7.8 years. All patients had unilateral involvement of ovaries. The most common presenting complaints included abdominal distension, abdominal pain and breathing difficulties. On per abdomen examination, mass per abdomen corresponded to uterus size ranging between 28-32 weeks. On bimanual examination, uterine size was not made out and fornical fullness due to the mass was noted. CA-125 levels were within the normal range for 3 out of the 5 patients whereas the other 2 had elevated levels (>35U/ml). CT imaging for 4 out of 5 cases showed features suggestive of malignancy, like multi-loculated cysts, ascites and solid components, though all of them were proved benign in the end. All the tumours were large in size ranging from 21 to 26 cm in greatest dimension. The various histopathology reports included borderline mucinous tumours (Fig. 1a, 2b, 3c), simple serous cyst (Fig. 1b), benign serous cystadenoma with torsion related changes (Fig. 3a, 3b) and benign seromucinous cystadenoma (Fig. 1c, 2a), with most common being benign serous cystadenoma.

Discussion

The ovary is a ductless reproductive gland in which the female reproductive cells are produced. With a normal size of 3 x 2 x 2 cm, it has nearly 1 million eggs at birth, which reduces to around 3 lakhs at puberty. This organ is also responsible for the secondary sexual characteristics of women by producing hormones, mainly oestrogen and progesterone. Menopause, which refers to the cessation of menstrual cycles, occurs after 45 years of age in most women. This makes them more prone to ovarian tumour due to the hormonal changes.

The incidence of ovarian tumours in post-menopausal women is commonly noted in the age group 60-80 years.4 The mean age of diagnosis in our study is 54.6 years, which is similar to a study by Jacobs et al.,13 where mean age was 56 years. The incidence of ovarian tumours in modern Chennai is around 6.1 per 100 000 females.2 The 5-year survival rate for ovarian malignancy is 30-40% as they are mostly inoperable at the time of diagnosis.8

Ovarian tumours may be benign, malignant or borderline malignant. The common benign ovarian tumours are functional cysts (i.e. follicular cysts, corpus luteum cysts, theca lutein cysts) and benign neoplasms (i.e. epithelial cell tumours, germ cell tumours, stromal tumours). The commonly seen benign ovarian tumours in post-menopausal women are serous cystadenoma, mucinous cystadenoma, sero-mucinous cystadenoma. In this case series, serous cystadenoma is found to be the most common, which complies well with the studies by Mondal et al6 and Rajavigneshwari N et al.8 However, as per a study by Soumini G et al.7 mucinous cystadenoma was the commonest benign ovarian tumour. 30% of all ovarian tumours are serous cystadenomas. They are multi-loculated, lined by columnar or cuboidal epithelium, filled with thin clear yellowish fluid, with or without papillary projections.

These tumours may be symptomatic or asymptomatic. As the size of the tumours increase, pressure symptoms like pain abdomen, abdominal distension and breathing difficulties develop in case of large tumours extending up to the xiphisternum. All patients in our study had pain abdomen and abdominal distension as their primary complaints and this was in sync with a study by Yogambal et al.5 Katke RD,19 who did a study on a post-menopausal woman with a huge dermoid cyst of weight 7 kg, also had abdominal distension as the primary complaint. So did Velanki Venkata Sujatha20 in her case report of a 66 year old South Indian post-menopausal woman with a giant ovarian serous cystadenoma weighing 23 kg, with abdominal distension and pain as her primary complaints.

These tumours are evaluated by testing for CA 125 levels and also a transvaginal ultrasound or CT imaging in case of large abdomino-pelvic ovarian tumours. Transvaginal ultrasound imaging is known to be the single most effective way of evaluating post-menopausal ovarian tumours.3 Ultrasound imaging shows the laterality and locularity of the cyst, blood flow, presence of any papillary projections, solid areas and ascites, suggesting the possibility of either a benign or malignant ovarian tumour. In a study by DePriest et al.15 3220 asymptomatic post-menopausal women underwent screening by transvaginal ultrasonography between 1987-1992, which showed a decrease in the staging of ovarian cancer at detection and also the mortality arising from ovarian cancer, hence proving its efficacy as a screening tool for ovarian cancer.

A study by O’Connell et al16 among 56 patients presenting with pelvic masses showed that CA-125 had a negative predictive value of 100%, suggesting that this test may be useful in identifying those patients with pelvic masses at a higher risk of malignancy. However, another study by Vasiliev et al.17 suggested that elevated serum CA 125 level by itself does not distinguish benign from malignant pelvic masses, which syncs with our study results. CA-125 levels were checked for all the patients in our study and 2 out of the 5 had values higher than 35 U/ml, suggestive of malignancy. Despite these contradicting values, all proved to be benign in the end.

Risk Malignancy Index (RMI) Score is calculated as a product of CA-125 value, Menopausal status (M) (pre-menopausal = 1 and post-menopausal= 3) and the Ultrasound score (U) (0- if no features, 1- if any one of the ultrasound features is present, 3- if 2 or more ultrasound features are present). RMI has a sensitivity of 85% and specificity of 97% with a cut-off level of 200.9,11 Here, the RMI score was in the benign range for 4 out of 5 cases which correlated with the histopathology report in the end.

Such huge ovarian masses with size more than 20 cm definitely warrants laparotomy with frozen section. Based on frozen section report, further steps like omental biopsies and lymph node dissection are decided. In our study, we have analysed that despite most of the patients having CA-125 levels suggesting a benign nature of the tumours, imaging studies portray the possibility of malignancy too. Hence, considering the large size of the tumours, patients were counselled about the need for laparotomy and frozen section as histopathology is the ultimate confirmatory means of arriving at a diagnosis and further management. This has a psychological impact on the patient as it makes them anxious with regards to the outcome.

While a study by Modesitt et al.12 showed that the risk of malignancy of ovarian tumours of size less than 10 cm among women aged more than 50 years is less than 0.1%, there aren’t enough studies to prove the risk of malignancy in large ovarian tumours >20 cm in size. Bailey et al.14 also studied that unilocular ovarian cysts <10 cm in diameter in asymptomatic postmenopausal women or women ≥50 years of age are associated with minimal risk for ovarian cancer. In contrast, complex ovarian cysts with wall abnormalities or solid areas are...
associated with a significant risk for malignancy. Likewise, another study by Rulin et al\textsuperscript{18} had 40 out of 63 tumours larger than 10cm, being malignant. However, a study by Srisilapakodety et al\textsuperscript{1} showed that large ovarian tumours of size more than 10cm need not always be malignant. Our study also shows that large ovarian tumours more than 20cm in size should be thoroughly evaluated, keeping the possibility of benign nature of the tumour in mind.

**Conclusion**

Large benign ovarian tumours extending up to the xiphisternum commonly present with abdominal distension. Imaging studies showing features suggestive of malignancy like solid components, ascites and multiloculated cyst may not necessarily precede a histopathology report confirming the same. Hence, large size of the tumours need not always pose a malignant potential. They have to be evaluated thoroughly, with the main modality of management being laparotomy with frozen section, to rule out malignancy and then follow up with the histopathology report. Creating awareness among post-menopausal women about annual regular health check-up can definitely lead to early diagnosis and accurate management at an early stage, thus improving the overall health of our population.
