Abstract

Introduction: Retinal vein occlusion is second most common retinal vascular disorder after diabetic retinopathy. BRVO caused due to occlusion of branch vein of retina with involvement of particular quadrant. On ophthalmoscopic examination patient will have retinal edema and or macular edema with superficial and deep retinal haemorrhages and venous dilatation within the affected sector. The most recognized risk factor for BRVO are age and systemic vascular disorders.

Materials and Methods: Prospective observational study was done for the period of one year. Patients more than 30 years of age attending ophthalmology OPD found to have BRVO were evaluated for various risk factors after taking consent. History and thorough eye examination were carried out including fundus photography and fluorescein angiography.

Results: In this study 38 patients of more than 30 years (32-75 years) found to have BRVO out of which 21 were male and 17 were female. 25 cases (65.78%) (p-value 0.0384) having hypertension, 8 case (21.05%) (p-value 0.135) having diabetes, 7 (18.42%) (p-value 0.04) were smokers, 13 (34.21%) (p-value 0.0008) were having altered lipid profile, 15 (65.22%) (p value < 0.001) out of 23 cases were having higher homocysteine level, 2 cases (5.26%) were alcoholics. All these diseases are causing BRVO in a combination.

Conclusion: With the help of modern instrument and technology branch retinal vein occlusion can be easily diagnosed and treated. It is a multi-factorial disease affect the eyes of an individual having hypertension with other risk factors like ageing, hyperlipidaemia, homocysteinemia etc. so beware of four H, higher age, hypertension, hyperlipidaemia, homocysteinemia

Keywords: BRVO, Diabetes mellitus, Hypertension, Homocysteinemia, Smoking.

Introduction

Retinal Vein Occlusion (RVO) is the second most common retinal vascular disorder after diabetic retinopathy. It is the most common macro vascular disease entity of retina seen in clinical practice. BRVO was first described by Leber a German ophthalmologist in 18771 since then there has been a disagreement on diagnostic features of this clinical entity. It is noted that two third of retinal vein occlusion develops supero-temporally and one third develops infero-temporally.2 The most recognized risk factors for BRVO are age and systemic vascular disorder. A very basic and important fact in pathogenesis of BRVO is that like all ocular vascular occlusion disorder BRVO is multifactorial in origin. Since most of the studies on BRVO performed in white populations.3 Limited studies have been performed in Asian populations hence this study is carried out to identify the risk factors of BRVO.

Materials and Methods

It is a prospective observational study carried out at tertiary care centre for period of 12 months.

Inclusion Criteria: All the patients of 30 years of age and older having BRVO. Those giving consent to enroll in study

Exclusion Criteria:
1. Subjects having proliferative diabetic retinopathy with vitreous haemorrhage (VH).
2. Subjects having VH corneal opacity and mature cataract.
3. Eyes with hemi retinal vein occlusion were excluded from study as regarded as CRVO.

Methodology

In this study patients of >30 years of age who diagnosed to have BRVO on routine fundus examination and having complain of sudden painless blurring of vision were evaluated.
1. Brief history of all patients including chief complain, origin, duration and progression of symptoms, associated systemic illness and their treatment were noted.
2. The patient’s history of ocular surgery was also determined.
3. V/A assessment was done.
4. IOP was measured by using NON-contact tonometry.
5. SLE and fundus examination by 78D and 20D was done.
6. The findings of fundus examination were recorded in terms of types of BRVO and location of it.
7. Confirmatory test - Fundus photograph, FFA We consider age, sex, hypertension, diabetes, smoking, alcohol intake, lipid profile, homocysteine level as possible risk factors for BRVO.

Hypertension was defined as BP > 140 to >90mm of Hg.
DM was defined as blood sugar > 125mg/dl, PPBS > 220mg/dl orHb1Ac >6.5homocysteinemia defined as level >15mmol/lit.

Results and Discussion
We have detected 38 patients having BRVO during our study for a period of 1 year, out of 38 BRVO cases 21 were male and 17 were female. Study shows male preponderance which is comparable in other studies higher hematocrit and hormonal basis in males could act as a contributory factor in elevating blood viscosity and producing BRVO. Gutenberg health study in 2015 shows that prevalence of RVO increases with age.

Risk Factors
Hypertension: 25 out of 38 cases of BRVO having history of hypertension. Out of these 9-patient were having hypertension only as a risk factor while 16 patients were detected hypertension associated with other risk factor during study period.

Lipid Profiles: Serum Lipid profiles alteration predisposes the vein for occlusive disease. Increase in LDL, TG and cholesterol and decrease in HDL put the vessels at risk of atherosclerosis and can lead to BRVO. In this study 13 out of 38 cases were having this risk factor having history of smoking. In the eye disease case control study smoking was a risk factor for BRVO

In BDES age adjusted current smoking (OR 4.43, 95% CI: 1.53,12.84) compared with nonsmokers. SINDI study and meta-analysis by Petr Kolar also has a similar finding.

Newman- Casey PA et al assessed the risk factors associated with developing BRVO, they found that HT alone or along with DM and hyperlipidemia had an increased hazard of developing a BRVO compared with those with none of these conditions.

Other studies mentioned that hypertension is having strong association with the occurrence BRVO Data of our BRVO cases also shows HT as a risk factor [25 cases out of 38, 65.79% at 95% CI: 48.65% to 80.37%] This finding is consistent with other case series reported 55% to 75% of BRVO.

Diabetes: There were 8 BRVO cases (21.05%, 95%, CI: 9.55% to 37.32%) in this study having history of diabetes at time of presentation 6 patients out of them were having RBS>140mg/dl while 2 patients were having blood glucose less than that. Out of total 8 diabetic cases 6 patients have associated hypertension so only 2 patients (5.26%, 95%, CI: 0.64% to 17.74%) affected BRVO were having DM only as a risk factor. Lam HD et al CIEMS study also shows that BRVO was not significantly associated with the presence of DM(P>0.10). Metanalysis by Petr Kolar shows that individual with end organ damage caused by DM having greatly increase risk of RVO i.e. CRVO only not BRVO.

Alcoholism and Smoking: 2 out of 38 cases (5.26%, 95%, CI: 0.64% to 17.74%) were having H/O alcoholism. Beaver dam eye study (BDES) does not consider alcohol consumption as a risk factor for BRVO and similar results found in CIEM study. 7 out of 38 cases (18.42%, 95% CI; 7.74% to 34.32%) were having blood glucose less than that. Out of total 8 diabetic cases 6 patients had got done serum homocysteine out of 38 patients. The normal value for S. Homocysteine 15mmol/lit. Out of 23
patients those who had undergone S. homocysteine level 15 patients were having high level of S. Homocysteine.

(Z test of proportion applied by using epitool software.)

1. Nine (23.68%) patients only having the hypertension in contrast to the sixteen (42.10%) patients are in the combination with other risk factor. (p value=0.0384).
2. Smoking in a combination can cause BRVO (p value=0.04).
3. Altered serum lipid profiles with other risk factors can cause BRVO (p value=0.0008).
4. Serum Homocysteine alone and in a combination, can cause BRVO (p value<0.001).
5. Out of 38 patients 18 patients are having multifactorial risk of BRVO, 15 patient having single disease while 5 patients do not have any disease.

Conclusion

It is observed that BRVO is a multifactorial disease which is common in males of above 40 years. Sedentary lifestyle and unhealthy dilatory habits increases the risk of hypertension and hyperlipidemia. Systemic hypertension, hyperlipidemia and homocysteinemia are main risk factors of BRVO out of which hypertension and homocysteinemia alone can cause BRVO.

Acknowledgement

I thankful to Dr. Swati Patel, assistant professor, community medicine for charting and calculations and residents of the ophthalmology department for their support.

A study by Kapil D Lahiri\(^{18}\) in India analyzed total plasma homocysteine in 64 cases of retinal vein occlusion of which 24 cases of central retinal vein occlusion and 40 cases of BRVO homocysteine was significantly in increase in RVO case in respect to control (p<0.001) S. homocysteine\(^{8,12}\) has been established as an independent risk factor for development of BRVO. Meta-analysis by Peter Kolar\(^{5}\) also supports these results.
