Abstract
Introduction: Mental foramen is a minute circular/oval shaped opening present bilaterally in the anterior surface of the body of the mandible. The mental foramen marks the termination of mandibular canal in the mandible, through which the inferior alveolar neurovascular bundle passes. Evaluation of the position of the mental foramen in various surgical procedures like fracture of body of mandible, nerve lateralization procedure, dental implant, orthognathic surgery etc. helps in preventing damage to neurovascular bundle thus preventing paresthesia of lower lip, gums and lower anterior teeth. The aim of this study was to determine the position of the mental foramen in the Muradnagar-Ghaziabad population using digital panoramic radiographs in order to keep a record of the variations of the morphologic features of the mental foramen in anethic population of Muradnagar.

Materials and Method: A total of 1000 digital orthopantomogram of 635 male and 365 female patients within the age group of 15 to 55 years were collected and the position of mental foramen along the vertical and horizontal axis was analyzed.

Results: The most common position of mental foramen was found to be in line with second premolar tooth (51%), in the horizontal axis and along the vertical axis, it was inferior to the apex of second premolar (68.1%).

Conclusion: This Study supports the earlier literature regarding the position of mental foramen among north Indian population and suggests that variations are present between populations of different geographical areas.

Keywords: Mental foramen, Orthopantomogram, Muradnagar-Ghaziabad Population.

Introduction
Mental foramen is a small round/oval structure present in the body of the mandible and is commonly seen apical to the second mandibular premolar or between the apices of the premolars. It opens in a posterior direction and the mental nerve and vessels supplying sensation to the lower lip and the labial mucosa traverses via the mental foramen. Studying the position and morphological variations of mental foramen is very important because it is a critical and distinctive landmark for localizing the neurovascular bundle passing through it, in order to perform meticulous osteotomies and dental implant placement without causing any neurosensory dysfunction. The most common position of the mental foramen is in line with the longitudinal axis of the second premolar tooth followed by the location between the first and second premolar tooth. In literature, the position of mental foramen is stated to vary with different races and populations, so the present study was undertaken, to determine the position of mental foramen among the population of Muradnagar city of Ghaziabad.

Materials and Method
Total of 1000 digital panoramic radiographs of 635 male and 365 female patients within the age group of 15-55 years who were advised for radiographs for various purposes were studied and the position of mental foramen was determined on the radiographs.

The radiographs were chosen according to the following criteria given in Table 1:

<table>
<thead>
<tr>
<th>Inclusion criteria</th>
<th>Exclusion criteria</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Orthopantomogram in which all mandibular teeth were present upto first molars.</td>
<td>• OPGs in which the lower teeth (between 36 and 46) were missing, presence of an endodontic lesion, root canal treatment or any restorations were left out because of possible associated periapical changes.</td>
</tr>
<tr>
<td>• OPGs showing all erupted teeth.</td>
<td>• Radiographs with missing lower canine were excluded.</td>
</tr>
<tr>
<td>• The films which did not have any radiolucent or radiopaque lesion in the lower jaw and presented no radiographic artifacts.</td>
<td>• Orthopantomogram of degraded quality with superimposition of structures.</td>
</tr>
</tbody>
</table>
The position (Vertical and Horizontal axis) of the mental foramen was recorded as follows: (Table 2)(4)

**Horizontal Axis (H)**

H-1: Position depicting the foramen anterior to the first premolar.
H-2: Position depicting the foramen along the line with the first premolar.
H-3: Position depicting the foramen between the premolars.
H-4: Position depicting the foramen along the line with the second premolar.
H-5: Position depicting the foramen between the second premolar and molar.

**Vertical Axis (V)**

V-1: Position depicting the foramen inferior to the apex of the first premolar.
V-2: Position depicting the foramen inferior to the apex of the second premolar.
V-3: Position depicting the foramen at the level of the apex of the first premolar.
V-4: Position depicting the foramen at the level of the apex of the second premolar.
V-5: Position depicting the foramen lying superior to the apex of the first premolar.
V-6: Position depicting the foramen lying superior to the apex of the second premolar.

**Results**

A total of 1000 OPGs were assessed, therefore radiologically 2000 mental foramen were assessed, 1000 on each side i.e., left and right. Mean age for males was 38.73 years and that for females were 34.43. The results are depicted in Graphs 1-3.

**Graph 1: Depicts the total number of male and female**

**Graph 2: Depicts percentage of the position of the mental foramen in the horizontal axis**

**Graph 3: Depicts percentage of position of mental foramen in the vertical axis**

**Discussion**

Mandible being the largest and strongest bone of facial region has evolved in morphology in homosapiens from primates through ages. The changes in size and shape of jaws have been studied immensely. The mandible shows extensive variation in its size, weight and location of bony structures during an individual’s lifetime. Morphological variations are also seen in mandible among different gender, ethnicities, and races. Out of all the components of the mandible, the identification of mental foramen holds a distinct primacy as an important landmark in numerous maxillofacial surgical procedures.(5) Mental foramen represents the terminal part of the mandibular canal and the mental nerve and vascular structures pass through it, supplying sensory innervation to the mucosa of lower lip, a vestibular region on the buccal aspect of lower jaw, and the gingival portion of lower jaw, of anterior region.(6,7) Placement of mandibular endosseous implants, pose a problem in the area of neurovascular bundles leading to certain complications, such as altered sensation, numbness and pain, often due to damage to structures, such as inferior alveolar nerve (IAN) and mental foramen. The damage of related vascular structures can lead to hemorrhage, which can be difficult to control. Damage to these structures is mostly arising from iatrogenic mistakes and sometimes due to failure in identification structures. Identification of mental foramen is also of utmost importance while administering regional anesthesia, performing genioplasties, placing cuts for orthognathic procedures, while performing corticotomies in nerve lateralization and apicectomy. Therefore, it is critical to determine the location and as well as the morphological configuration of the IAN canal and foramen, in order to minimize the damages.

In the present study, the most common position of mental foramen was found to be in line with second premolar tooth (51%) on the horizontal axis and in the vertical axis, it was found to be inferior to the apex of the second premolar (68.1%). (Table 3)

Conclusion
The location of mental foramen, most commonly found in Muradnagar population, was in line with second premolar tooth, along the horizontal axis and in the vertical axis, it was found to be inferior to the apex of the second premolar. The shape of the mental foramen was circular in most of the OPG’s and the foramina were observed to be bilaterally symmetrical. Our findings are congruous with earlier data reviewed in literature in different populations among different varied geographic locations. It is discernible from the previous vast literary works, that the location of the mental foramen is indeed differed among different races. Accordingly, our study may add the valuable data regarding mental foramen position among different races and can provide handy inputs to the maxillofacial surgeons and dental practitioners to identify and locate it so as to accomplish uneventful surgical procedures.
