Article Info

Abstract

The wide range of applications of cooling fins are evident in heat transfer enhancements for various thermal systems and also, for the control and prevention of thermal damages in mechanical and electronic equipment. In this work, nonlinear thermal behaviour of convective-radiative cooling fin with convective tip and subjected to magnetic field is analyzed using Galerkin finite element method. The numerical solutions are verified by the exact analytical solution of the linearized models using Laplace transforms method. Based on the numerical investigations, it is established that increase in Biot number, convective, radiative and magnetic parameters increase the rate of heat transfer from the fin and consequently improve the efficiency of the cooling fin. Also, the study shows that for a relatively short cooling fin operating for prolonged periods of time or steady state, the adiabatic/hypothetical condition (or negligible heat transfer) at the tip can be assumed without any significant loss in accuracy or equality as compared to the convective condition at the tip. However, for a long cooling fin of finite length operating in a transient state, especially for short period of time, the assumption of insulated tip produces significant different results as compared to the results of the convective tip. Therefore, for transient thermal studies of fins, the assumption that no heat transfer takes place at the fin tip should be taken with caution for a long cooling fin of finite length operating within a relatively short period of time. It is hope that the present study will enhance the understanding of transient thermal response of the solid fin under various factors and fin tip conditions.

1. Introduction

The increasing demands for high performance thermal equipment require the development of enhanced heat transfer devices. Also, the generation of excessive heat that leads to thermal-induced failure in various thermal systems calls for the production of effective heat dissipating devices that will enhance the rate of heat transfer from the thermal equipment. In order to meet these needs, extended surfaces such as fins and spines have been applied in various thermal and electronic equipment. Consequently, the applications of the extended surfaces in the thermal systems such as air conditioning, refrigeration, super heaters, automobile, power plants, heat exchangers, convectional furnaces, economizers, gas turbines, chemical processing equipment, oil carrying pipelines, computer processors, electrical chips, electronic and microelectronics components, high-power semi-conductor devices, high-power lasers, light emitting diodes (LEDs), computer cooling, sensitive devices etc. have attracted various research interests in few past decades. The thermal analysis of the extended surfaces involves the development of thermal models for various operating conditions. Different analytical
(exact and approximate) and numerical methods have been employed by various researchers to analyze the developed thermal models of the extended surfaces. Exact analytical methods such as methods of superposition and separation of variables were employed by Wang et al. [1] while Moitsheki and Harley [2], Mhlongo and Moitsheki [3], Ali et al. [4] and Kader et al. [5] adopted Lie point symmetry method for the thermal analysis of fins. Kirchhoff's transformation method was adopted by Moitsheki and Rowjee [6]. In an earlier work, Cole et al. [7] made use of Green's functions (GF) in the form of infinite series to present analytical solutions to the differential equations governing the thermal behaviour of fins.

The above reviewed works provided exact analytical solutions to the thermal models governing the thermal behaviours of the fins under various operating conditions. However, most of the developed exact analytical solutions are based on the assumptions of constant thermal properties. Indubitably, the idealization of a constant or uniform heat transfer coefficient is not realistic. This is because in practice, heat transfer coefficients have significantly greater values at the fin tip more than the fin base. Additionally, the heat transfer coefficients vary with temperature. Such variation of the heat transfer coefficient as a function of temperature is often governed by a power law. Moreover, the thermal conductivity of the fin is temperature-dependent. Under these circumstances, the differential equations governing the thermal responses of the fin under various conditions become strictly nonlinear. Therefore, large numbers of the past studies have applied various approximate analytical methods to solve the nonlinear thermal models under various geometrical, internal and external conditions. In past few decades, Jordan et al. [8] utilized optimal linearization method while Kundu and Das [9] adopted Frobenius expanding series for the nonlinear fin problems. Homotopy analysis method was used by Khani et al. [10] and Amirkolaei and Ganji [11]. Aziz and Bouaziz [12] employed method of least squares while Sobamowo [13], Ganji et al. [14] and Sobamowo et al. [15] applied Galerkin method of weighted residual to analyze the thermal behaviour of the extended surfaces. In recent times, double decomposition and variation of parameter methods were employed by Sobamowo [16] and Sobamowo et al. [17], respectively to investigate the heat transfer characteristics of fins. In some other works, Moradi and Ahmadiakia [18], Sadri et al. [19], Ndlovu and Moitsheki [20], Mosayebidarchech et al. [21], Ghasemi et al. [22] and Ganji and Dogonchi [23] adopted differential transformation method to determine the temperature distribution in fins. Applications of homotopy perturbation method to the fin problem was presented by Sobamowo et al. [24], Arslanturk [25], Ganji et al. [26] and Hoshyar et al. [27].

The developed series solutions for the thermal analyses of fins using different approximate analytical methods involve large number of terms. In practice, such expressions involving large number of terms are not convenient for use by designers and engineers [13]. Therefore, over the years, various numerical methods have been explored to analyze the thermal behavior of various extended surfaces. In an earlier work on numerical analysis of determination of temperature distribution in fins, Singh et al. [28] adopted meshless element free Galerkin method. Few years later, Basri et al. [29] presented a study on the applications of efficient finite element and differential quadrature methods to the heat transfer problems. Singh et al. [30] and Sao and Banjare [31] used quasi- steady theory while in the same year, Lotfi and Belkacem [32] and Al- Rashed et al. [33] utilized finite volume method for the thermal analysis of fins. In another study, Taler and Taler [34] presented the coupling of finite volume finite element methods to the heat transfer problem. Incremented differential quadrature method was used by Malekzadeh and Rahideh [35]. Reddy et al. [36] adopted B- spline based finite element method while Sun et al. [37] applied collocation spectral method to the fin problem. Rajul et al. [38] examined the thermal response of the fin using Meshless Local Petrov-Galerkin (MLPG). In the
preceding year, Wei et al. [39] investigated the thermal behaviour of fin through field synergy principle optimization analysis. Hajabdollahi et al. [40] presented genetic algorithm while symbolic programming was used by Fatoorehchi and Abolghasemi [41]. Three years later, Latif et al. [42] successfully applied symmetry reduction method to address nonlinear heat transfer problems of fins. In the same year, Mahmoudi and Mejri [43] used to Lattice Boltzmann method to investigate the effect of variable thermal conductivity and variable refractive index on transient conduction and radiation heat transfer. In some recent studies, Sobamowo [44] and Sobamowo et al. [45] applied finite difference and finite volume method, respectively for thermal analysis of longitudinal fin with temperature-dependent thermal conductivity and internal heat generation. Also, Sobamowo et al. [46] and Sobamowo [47] adopted Legendre wavelet collocation method to investigate the effects of magnetic field on the thermal performance of convective-radiative fin and also to study heat transfer in porous fin with temperature-dependent thermal conductivity and internal heat generation. Sobamowo and Kamiyo [48] studied multi-boiling heat transfer behavior of a convective straight fin with temperature-dependent thermal properties and internal heat generation using finite volume method. In another study, Chebychev spectral collocation method was used by Sobamowo [49] to examine the heat transfer in porous fin with temperature-dependent thermal conductivity and internal heat generation.

It should be noted that most of the above reviewed studies are based on steady state analysis of fin. However, in many engineering practices and devices such as in automobiles, study of heat transfer in building, industrial applications, transient analysis is very important. In fact, an accurate transient analysis provides insight into the design of fins that would fail in steady-state operations but are sufficient for desired operating periods. Consequently, there have been comparatively few studies on the transient analysis of the fin. In some earlier works, transient closed form solutions were developed for fin with assumed constant thermal properties. Chapman [50] studied the transient behavior of an annular fin of uniform thickness subjected to a sudden step change in the base temperature. Few years later, Donaldson and Shouman [51] presented a study on the transient temperature distribution in a straight fin for a step change in base temperature and a step change in base heat flow rate. Also, in a subsequent works, Suryanarayana [52,53] investigated the transient response of straight fins of constant cross-sectional area. Mao and Rooke [54] utilized Laplace transform method to analyze straight fins for different cases of a step change in base temperature, a step change in base heat flux and a step change in fluid temperature. Method of Green's functions was adopted by Beck et al. [55] to study transient behavior of fins of constant cross-section area. In an earlier work, Kim [56] developed an approximate solution to the transient heat transfer in straight fins of constant cross-sectional area and constant physical and thermal properties. Three years later, Aziz and Na [57] examined the transient response of a semi-infinite fin of uniform thickness, initially at the ambient temperature, subjected to a step change in temperature at its base, with fin cooling governed by a power-law type dependence on temperature difference. In another work, Aziz and Kraus [58] presented a variety of analytical results for transient fins, developed by separation of variable and Laplace transform techniques. Campo and Salazar [59] explored the analogy between the transient conduction in a planar slab for short times and the steady state conduction in a straight fin of uniform cross-section. Saha and Acharya [60] submitted a detailed parametric analysis of the unsteady three-dimensional flow and heat transfer in a pin-fin heat exchanger. Furthermore, several numerical studies of transient fins combined with complicating factors, such as natural convection [61, 62], spatial arrays of fins [63, 64] and phase change materials [65] have been presented. Mutlu and Al-Shemmeri [66] studied a longitudinal array of straight fins suddenly heated at the base.
In the above reviewed studies, heat dissipation from the fin tip has been assumed negligible. Therefore, the analyses of the reviewed works were based on fins with insulated tips or negligible heat transfer at the tips. However, effects of fin tip on the thermal response and performance of the fin have been pointed out in some few studies in literature. In such studies, Irey [67], Laor and Kalman [68], Lau and Tau [69] and Ünal [70] examined fins that dissipate heat also by their tips with constant or various temperature-dependence heat coefficients under steady state conditions.

Sequel to the above, there have been various studies on the thermal analysis of fin. However, there are limited studies in literatures on the applications of finite element methods for transient heat transfer analysis of fin with convective tip and under the influence of magnetic field. Therefore, in this present study, Galerkin finite element method is used study the transient thermal behavior of convective-radiative fin with convective tip and under the influence of magnetic field. The inherent advantages, wide range of applications and high level of accuracy of the method justify the consideration of the method for the problem under consideration. FEM is geometrically flexible and it enjoys an advantage in memory use and speed for large problems. It can handle Neumann boundary condition as readily as the Dirichlet boundary condition as demonstrated in the present study. Of all the numerical methods developed so far, the finite-element method has been found to be the most general method, not only to solve the problems of heat transfer but also to solve various problems in different areas of engineering and science. Finite element method provides superior versatility to other numerical methods and is generally very stable with excellent convergence characteristics. To the best of the authors’ knowledge, the transient analysis of heat transfers in convective-radiative cooling fin with convective tip and subjected to magnetic field using finite element method has not been studied in open literature. As part of the aims of the present paper, a step-by-step finite element analysis is presented in this work. The numerical solutions are used to investigate the effects of convective, radiative, magnetic and convective tip parameters on the transient thermal performance of the cooling fin. Also, effect the thermal stability values for the various multi-boiling heat transfer modes are established.

2. Problem formulation

Consider a straight fin of length L and thickness t which is exposed on both faces to a convective-radiative environment at temperature $T_\infty$ and subjected to a uniform magnetic field as shown in Fig.1. In order to develop the mathematical model governing the thermal behavior, the following assumptions are made:

I. The fin material is homogeneous and isotropic and with constant physical properties.

II. The thermal properties of the fin, surrounding medium and the magnetic field vary with temperature according to power-law. The temperature of the surrounding fluid is uniform.

III. The heat flow to or from the fin surface at any point is directly proportional to the temperature difference between the surface at that point and the surrounding fluid.

IV. The fin thickness is so small compared to its height and length that temperature gradients normal to the surface (across the fin thickness) may be neglected. Therefore, the temperature variation inside the fin is one-dimensional i.e. temperature varies along the fin length only. heat loss through the fin edges is negligible compared to that which passes through the sides.

V. There is no contact resistance where the base of the fin joins the prime surface. Also, the temperature of the base of the fin is uniform.
VI. There are no heat sources or internal heat generation within the fin.

Based on following the above assumptions, the thermal energy balance could be expressed

\[ q_x - \left( q_x + \frac{\delta q}{\delta x} \right) dx = h(T)P(T - T_{\infty})dx + \sigma\varepsilon(T)P(T^4 - T_{\infty}^4)dx + \frac{J_c \times J_c}{\sigma} dx + \rho A_{cr} c_p \frac{\partial T}{\partial t} dx \]  

(1)

Where;

\[ J_c = \sigma (E + V \times B) \]  

(2)

As \( dx \to 0 \), Eq. (1) reduces

\[ -\frac{dq}{dx} = h(T)P(T - T_a) + \sigma\varepsilon(T)P(T^4 - T_{a}^4) + \frac{J_c \times J_c}{\sigma} + \rho A_{cr} c_p \frac{\partial T}{\partial t} \]  

(3)

From Fourier’s law of heat conduction, the rate of heat conduction in the fin is given by

\[ q = -kA_{cr} \frac{dT}{dx} \]  

(4)

Following, the radiation heat transfer rate is

\[ q = -kA_{cr} \frac{dT}{dx} \]  

(4)

\[ q = \frac{4\sigma A_{cr} dT^4}{3\beta_R \frac{dx}{dx}} \]  

(5)

Therefore, the total rate of heat transfer is given by;

\[ q = -kA_{cr} \frac{dT}{dx} - \frac{4\sigma A_{cr} dT^4}{3\beta_R \frac{dx}{dx}} \]  

(6)

On substituting Eq. (6) into Eq. (3), one gets
Further simplification of Eq. (7) gives the governing differential equation for the fin as

\[
\frac{d^2 T}{dx^2} + \frac{4\sigma}{3\beta_k} \frac{d}{dx} \left( \frac{dT^4}{dx} \right) - \frac{h(T)P}{kA_{cr}} (T - T_\infty) - \frac{\sigma \varepsilon(T) P}{kA_{cr}^2} (T^4 - T_\infty^4) = 0
\]  

(8)

The initial and boundary conditions are

\[
\begin{align*}
t & = 0, & 0 < x < b, & T = T_b, \\
t & > 0, & x = 0, & T = T_{b0}, \\
t & > 0, & x = b, & -k \frac{dT}{dx} = h(T - T_\infty)
\end{align*}
\]

(9a)

However, if the tip of the fin is assumed insulated or a negligible rate of heat transfer from it, we have

\[
t > 0, & \quad x = b, & \frac{dT}{dx} = 0
\]

(9b)

It should be noted that

\[
\frac{J_c \times J_c}{\sigma} = \sigma_m B_0^2 u^2
\]

(10)

After substitution of Eq. (10) into Eq. (8),

\[
\frac{d^2 T}{dx^2} + \frac{4\sigma}{3\beta_k} \frac{d}{dx} \left( \frac{dT^4}{dx} \right) - \frac{h(T)P}{kA_{cr}} (T - T_\infty) - \frac{\sigma \varepsilon(T) P}{kA_{cr}^2} (T^4 - T_\infty^4) = 0
\]

(11)

The first case that is considered in this work is a situation where small temperature difference exists within the fin material during the heat flow. This actually necessitated the use of temperature-invariant physical and thermal properties of the fin. Also, it has been established that under such scenario, the term \(T^4\) can be expressed as a linear function of temperature. Therefore, we have

\[
T^4 = T_\infty^4 + 4T_\infty^3(T - T_\infty) + 6T_\infty^2(T - T_\infty)^2 + \ldots \equiv 4T_\infty^3 T - 3T_\infty^4
\]

(12)

Also, using Rosseland’s approximation

\[
\frac{4\sigma}{3\beta_k} \frac{dT^4}{dx} \approx \frac{16\sigma T_\infty^3}{3\beta_k} \frac{d^2 T}{dx^2}
\]

(13)

On substituting Eqs. (15) and (16) into Eq. (14), we arrived at

\[
\begin{align*}
\frac{d^2 T}{dx^2} + \frac{16\sigma T_\infty^3}{3\beta_k} \frac{d^2 T}{dx^2} & = \frac{h(T)P}{kA_{cr}} (T - T_\infty) - \frac{4\sigma P \varepsilon(T) T_\infty^3}{kA_{cr}} (T - T_\infty) \\
- \frac{\sigma_m(T) B_0^2 u^2}{kA_{cr}} (T - T_\infty) & = \frac{\rho c_p \varepsilon(T)}{k} \frac{dT}{dt}
\end{align*}
\]

(14)

However, for most industrial applications, the heat transfer coefficient may be given as the power law [2,19], where the exponent \(p\) and \(h_0\) are constants. The constant \(p\) may vary
between \(-6.6\) and \(5\). However, in most practical applications it lies between \(-3\) and \(3\) [19]. So, the power temperature-dependent thermal properties of the surrounding fluid and the magnetic field are defined as

\[
h(T) = h_0 \left( \frac{T - T_\infty}{T_b - T_\infty} \right)^p
\]

(15)

Extending the same power temperature-dependent relationship to the fin emissivity and the magnetic field, we have

\[
\varepsilon(T) = \varepsilon_0 \left( \frac{T - T_\infty}{T_b - T_\infty} \right)^q
\]

(16)

\[
\sigma_m(T) = (\sigma_m)_0 \left( \frac{T - T_\infty}{T_b - T_\infty} \right)^r
\]

(17)

The exponent \(p\) on the heat transfer coefficient represents laminar film boiling or condensation when \(p = -1/4\), laminar natural convection when \(p = 1/4\), turbulent natural convection when \(p = 1/3\), nucleate boiling when \(p = 2\), radiation when \(p = 3\). \(p = 0\) implies a constant heat transfer coefficient.

Substitution of Eq. (16) - (17) gives

\[
d^2T \over dx^2 + \frac{16\sigma}{3\beta_k k} d^2T \over dx^2 - \frac{h_0 P(T - T_\infty)^{p+1}}{k A_{cr}(T_b - T_\infty)^p} - \frac{4\sigma\varepsilon_0 P T_\infty^3 (T - T_\infty)^{q+1}}{k A_{cr}(T_b - T_\infty)^q}
\]

\[
- \sigma_m B_o^2 u^2 (T - T_\infty)^{r+1} \over k A_{cr}(T_b - T_\infty)^r = \rho c_p \over k \partial T \over \partial t
\]

(18)

For constant thermal properties of the surrounding fluid and the magnetic field, we have a linear equation of the form

\[
d^2T \over dx^2 + \frac{16\sigma}{3\beta_k k} d^2T \over dx^2 - \frac{h_0 P(T - T_\infty)}{k A_{cr}} - \frac{4\sigma\varepsilon_0 P T_\infty^3 (T - T_\infty)}{k A_{cr}}
\]

\[
- \sigma_m B_o^2 u^2 (T - T_\infty) \over k A_{cr} = \rho c_p \over k \partial T \over \partial t
\]

(19)

It should be noted that the above Eq. (19) can be solved analytically. Using Laplace transform, it can easily be shown that the exact analytical solution of the equation based on the boundary conditions in Eq. (9) is given as;

\[
 T = T_\infty + (T_b - T_\infty) \over \begin{cases}
\left(\frac{(h_p + 4\sigma A_{cr} T_\infty^3 B_o^2 u^2)}{A_{cr} k + 16 A_{cr} T_\infty^3 B_o^2 u^2}\right) \cosh\left(\frac{(h_p + 4\sigma A_{cr} T_\infty^3 B_o^2 u^2)}{A_{cr} k + 16 A_{cr} T_\infty^3 B_o^2 u^2}\right) (L-x) + \left(\frac{h_b L}{k}\right) \sinh\left(\frac{(h_p + 4\sigma A_{cr} T_\infty^3 B_o^2 u^2)}{A_{cr} k + 16 A_{cr} T_\infty^3 B_o^2 u^2}\right) (L-x)
\end{cases}
\]

\[
-2 \sum_{m=1}^{\infty} \begin{cases}
\lambda_m^2 \sinh\left(\frac{\lambda_m L}{k}\right) \exp\left(-\lambda_m^2 \frac{(h_p + 4\sigma A_{cr} T_\infty^3 B_o^2 u^2)}{A_{cr} k + 16 A_{cr} T_\infty^3 B_o^2 u^2}\right) \left(\frac{(k + 16 A_{cr} T_\infty^3 B_o^2 u^2)}{\rho c_p L_x}\right)^2
\end{cases}
\]

(20a)

For the insulated tip, we have
$T = T_\infty + (T_b - T_\infty) \begin{cases} \frac{(hP + 4\sigma t T_0^3 P + \sigma_m P B_0^2 u^2)L}{Ae(k + \frac{16\sigma}{3PR})} \cos(hP + 4\sigma t T_0^3 P + \sigma_m P B_0^2 u^2)L(k + \frac{16\sigma}{3PR})} \cosh(\frac{(hP + 4\sigma t T_0^3 P + \sigma_m P B_0^2 u^2)L}{Ae(k + \frac{16\sigma}{3PR})}) \\ \sum_{n=1}^{\infty} \frac{\lambda_n^{2L} \sin(\frac{\lambda_n L}{L})}{t} \left( \lambda_n^2 + \frac{(hP + 4\sigma t T_0^3 P + \sigma_m P B_0^2 u^2)L}{Ae(k + \frac{16\sigma}{3PR})} \right)^2 \left( \frac{k + \frac{16\sigma}{3PR}}{\rho c^2 p L^2} \right) \right) \end{cases}$

(20b)

where $\lambda_n$ are the positive roots of the characteristic’s equation

$$\lambda_n \cos \lambda_n + \left( \frac{hL}{k} \right) \sin \lambda_n = 0 \quad (21a)$$

It should be noted that a steady state is attained when $t \to \infty$

For the sake of convenience in subsequent analysis, it should be noted that “$b$” has been replaced with “$L$” in the above analytical solution.

3. Finite Element Method for the Transient Analysis

It is very difficult to develop exact analytical solution to the nonlinear equation in Eq. (14) or Eq. (18). Therefore, Galerkin finite element method is used in this work to solve the nonlinear equation. The procedures of the numerical method are outlined as follows:

I. **Finite element discretization:** The whole domain is divided into a finite number of sub-domains, designated as the discretization of the domain. Each sub-domain is called an element. The collection of elements comprises the finite-element mesh.

II. **Generation of the element equations:** From the mesh, a typical element is isolated and the variational formulation of the given problem over the typical element is constructed. An approximate solution of the variational problem is assumed and the element equations are generated by substituting the assumed solution in the formulation. The element matrix, which is called stiffness matrix, is constructed by using the element interpolation functions.

III. **Assembly of element equations:** The algebraic equations obtained from the element matrix are assembled by imposing the inter-element continuity conditions. This yields a large number of algebraic equations known as the global finite element model, which governs the whole domain.

IV. **Imposition of boundary conditions:** The essential and natural boundary conditions as given in the problem under consideration are imposed on the assembled equations.

V. **Solution of assembled equation:** The assembled equations after the imposition of the boundary conditions are solved by any numerical technique that is developed for solving systems of linear equations. The numerical techniques are
Gaussian elimination method, Gauss-Jordan iterative method, Gauss-Jacobi iterative method, Gauss-Seidel iterative method, LU decomposition method, Choleski decomposition, Crout’s method, Householder’s technique, etc.

In order to demonstrate the application of the finite element method to the present nonlinear problem, a weak formulation of the nonlinear governing differential equation is derived using Galerkin finite element method. For the purpose of the finite element analysis, one can rewrite Eq. (14) as:

\[
\left( k + \frac{16\sigma}{3\beta_R} \right) \frac{d^2T}{dx^2} - \left( \frac{h(T)P + 4\sigma(T)e_oT_\infty^3 + \sigma_m(T)B_\infty^2u^2}{A_{cr}} \right) (T - T_\infty) \tag{21b}
\]

where temperature-dependent thermal properties of the surrounding fluid and the magnetic field are defined in Eqs. (15) – (17). Using the shape/interpolating function on the governing equation and integrating over the domain V of the control volume according to Galerkin finite element method, we have

\[
\int_V W \left( k + \frac{16\sigma}{3\beta_R} \frac{d^2T}{dx^2} - \left( \frac{h(T)P + 4\sigma(T)e_oT_\infty^3 + \sigma_m(T)B_\infty^2u^2}{A_{cr}} \right) (T - T_\infty) \right) dV = 0 \tag{22}
\]

For the one-dimensional problem which the dependent variable varies only along x-axis and the boundary integrals turn to be a point value on the boundaries, one can replace, dV by A_cr dx in the Eq. (22). Here, A_cr is the uniform cross-sectional area of the fin and P is the perimeter of the fin from which convection takes place.

\[
\int_L W \left( k + \frac{16\sigma}{3\beta_R} \frac{d^2T}{dx^2} A_{cr} \right) dx - \int_L \left( \frac{h(T)P + 4\sigma(T)e_oT_\infty^3}{A_{cr}} \right) P (T - T_\infty) dx
\]

\[- \int_L \sigma_m(T)B_\infty^2u^2(T - T_\infty) dx - \int_L \rho c \frac{dT}{dt} A_{cr} dx = 0 \tag{24}
\]

After expansion, one arrives at

\[
\int_0^L W \left( k + \frac{16\sigma}{3\beta_R} A_{cr} \frac{d^2T}{dx^2} - \left( \frac{h(T)P + 4\sigma(T)e_oT_\infty^3}{A_{cr}} \right) P (T - T_\infty) \right) dx = 0 \tag{25}
\]

The expansion of Eq. (24) gives

\[
\int_0^L W \left( k + \frac{16\sigma}{3\beta_R} A_{cr} \frac{d^2T}{dx^2} - \left( \frac{h(T)P + 4\sigma(T)e_oT_\infty^3}{A_{cr}} \right) P (T - T_\infty) \right) dx - \int_0^L \frac{h(T) + 4\sigma(T)e_oT_\infty^3}{A_{cr}} P W T dx + \int_0^L \sigma_m(T)B_\infty^2u^2 W T dx - \int_0^L \frac{h(T) + 4\sigma(T)e_oT_\infty^3}{A_{cr}} P T W dx - \int_0^L \sigma_m(T)B_\infty^2u^2 W T dx = 0 \tag{26}
\]

For the term (1) in Eq. (26), one can write
\[
\int_0^L W \left( k + \frac{16\sigma}{3\beta_R} \right) A_{cr} \frac{\partial T}{\partial x} \, dx = \left( k + \frac{16\sigma}{3\beta_R} \right) A_{cr} \int_0^L W \frac{\partial T}{\partial x} \, dx
\]  
(27)

Applying integration by part \((\int_0^L u \partial v = u v|_0^L - \int_0^L \partial v \, du)\) to Eq. (27), where;

\[
W = \frac{\partial u}{\partial x} = \frac{\partial W}{\partial x} \text{ and } v = \frac{\partial T}{\partial x}
\]

(28)

Applying Eq. (28) in Eq. (27), gives

\[
\int_0^L \left( k + \frac{16\sigma}{3\beta_R} \right) A_{cr} W \frac{\partial T}{\partial x} \, dx = \left( k + \frac{16\sigma}{3\beta_R} \right) A_{cr} \int_0^L W \frac{\partial T}{\partial x} \, dx
\]

\[= \left( k + \frac{16\sigma}{3\beta_R} \right) A_{cr} \left\{ W \frac{\partial T}{\partial x}\bigg|_0^L - \int_0^L \frac{\partial W}{\partial x} \frac{\partial T}{\partial x} \, dx \right\}
\]

(29)

Substituting Eq. (29) into Eq. (26), leads to

\[
A_{cr} \left( k + \frac{16\sigma}{3\beta_R} \right) \frac{\partial T}{\partial x}\bigg|_0^L W - \int_0^L \left( k + \frac{16\sigma}{3\beta_R} \right) A_{cr} \frac{\partial W}{\partial x} \frac{\partial T}{\partial x} \, dx
\]

\[= \int_0^L (h(T) + 4\sigma(T)\varepsilon^3_{T\infty})\rho c_p A_{cr} \frac{\partial T}{\partial t} \, dx - \int_0^L \sigma_m(T)B_0^2 u^2 WT \, dx + \int_0^L \left( h(T) + 4\sigma(T)\varepsilon^3_{T\infty} \right) \rho c_p A_{cr} \frac{\partial T}{\partial t} \, dx = 0
\]

(30)

Eq. (30) can be written as

\[
\int_0^L \rho c_p A_{cr} \frac{\partial T}{\partial t} \, dx + \int_0^L \left( k + \frac{16\sigma}{3\beta_R} \right) A_{cr} \frac{\partial W}{\partial x} \frac{\partial T}{\partial x} \, dx + \int_0^L (h(T) + 4\sigma(T)\varepsilon^3_{T\infty})\rho c_p A_{cr} \frac{\partial T}{\partial t} \, dx
\]

\[+ \int_0^L \sigma_m(T)B_0^2 u^2 WT \, dx
\]

\[= \int_0^L (h(T) + 4\sigma(T)\varepsilon^3_{T\infty})\rho c_p A_{cr} \frac{\partial T}{\partial t} \, dx + \int_0^L \sigma_m(T)B_0^2 u^2 WT \, dx + \int_0^L \left( k + \frac{16\sigma}{3\beta_R} \right) \rho c_p A_{cr} \frac{\partial T}{\partial t} \, dx
\]

\[= \int_0^L \left( k + \frac{16\sigma}{3\beta_R} \right) \rho c_p A_{cr} \frac{\partial T}{\partial t} \, dx
\]

(31)

The above Eq. (31) is a weak formulation of the nonlinear governing differential equation.

In order to carry out the finite element discretization as stated in the step 1 of the finite element analysis, the whole domain is divided into a finite number of sub-domains as shown in Fig. 2. For a one-dimensional problem, linear elements are used. The finite element discretization is done in a way such that the given length of the body is divided into number of divisions, say ‘n’ elements which consequently, gives \((n + 1)\) nodes to represent the body as shown in Table 1.

In the finite element analysis of the present problem (one-dimension transient state), 2-node linear elements are used and the given length of the fin is divided into 50 elements which give 51 nodes to represent the total length of the fin as shown in Table 2 and Fig. 2.

In order to construct a variational formulation of the given problem over an element, a typical element is isolated (Fig. 3) from the mesh shown in Fig. 2. The typical 2-node linear element with end nodes ‘i’ and ‘j’ having the corresponding temperature being denoted by $T_i$ and $T_j$, respectively is shown in Fig. 3.

For the 2-node element, the following analysis for the variational formulation is carried out. Following Eq. (31), it could be stated that the weak form formulation of the governing Equation for an element of length "$L_e$" is given as

$$
\int_0^{L_e} \rho c_p A_c r \frac{\partial T}{\partial t} dx + \int_0^{L_e} \left( k + \frac{16\sigma}{3\beta R} \right) A_c r \frac{\partial W}{\partial x} \frac{\partial T}{\partial x} dx + \int_0^{L_e} (h(T) + 4\sigma(T) \varepsilon_o T_o^3) P W T \frac{\partial W}{\partial x} dx \\
+ \int_0^{L_e} \sigma_m(T) B_o^2 u^2 W T \frac{\partial W}{\partial x} dx \\
= \int_0^{L_e} (h(T) + 4\sigma(T) \varepsilon_o T_o^3) P T_o W dx + \int_0^{L_e} \sigma_m(T) B_o^2 u^2 W T_o \frac{\partial W}{\partial x} dx + A_c r \left( k + \frac{16\sigma}{3\beta R} \right) \frac{\partial T}{\partial x} \bigg|_0^{L_e} W
$$

The linear temperature variation in the element is represented by

$$
T = \lambda_1 + \lambda_2 x
$$
where \( T \) is the temperature at any location \( x \) and the parameters \( \lambda_1 \) and \( \lambda_2 \) are constants. Since there are two arbitrary constants in the linear representation, it requires only two nodes to determine the values of \( \lambda_1 \) and \( \lambda_2 \). Thus, we have

\[
T_i = \lambda_1 + \lambda_2 x_i \\
T_j = \lambda_1 + \lambda_2 x_j
\]  

(34a) (34b)

On solving Eq. (34a) and (34b), we have

\[
\lambda_1 = \frac{r_i x_j - r_j x_i}{x_j - x_i}, \quad \lambda_2 = \frac{r_j - r_i}{x_j - x_i}
\]

(35)

After substituting the values of \( \lambda_1 \) and \( \lambda_2 \) in Eq. (35) into Eq. (33), one arrives at

\[
T = T_i \left( \frac{x_j - x}{x_j - x_i} \right) + T_j \left( \frac{x - x_i}{x_j - x_i} \right)
\]

(36)

The above Eq. (36) can be written as

\[
T = T_i W_i + T_j W_j = [W_i \ W_j] \begin{bmatrix} T_i \\ T_j \end{bmatrix}
\]

(37)

Where

\[
W_i = \frac{x_j - x}{x_j - x_i}, \quad W_j = \frac{x - x_i}{x_j - x_i}
\]

(38)

\( W_i \) and \( W_j \) are called shape/interpolation/test/basis functions. Furthermore, one can write Eq. (37) as;

\[
T = [W] \{T\}
\]

(39)

Where;

\[
[W] = \begin{bmatrix} W_i & W_j \end{bmatrix}
\]

(40)

is the shape function matrix and

\[
\{T\} = \begin{bmatrix} T_i \\ T_j \end{bmatrix}
\]

(41)

is the vector of unknown temperatures taking

\[
x_i = 0, \quad x_j = L_e, \quad \Rightarrow x_j - x_i = L_e
\]

(42)

Substitute Eq. (42) into Eq. (38), we have the shape functions as;

\[
W_i = 1 - \frac{x}{L_e}, \quad W_j = \frac{x}{L_e}
\]

(43)

On substituting Eq. (43) into Eq. (37), we can see that the temperature at any point "x" in the 2-node element is approximated by;

\[
T = \left(1 - \frac{x}{L_e}\right) T_i + \left(\frac{x}{L_e}\right) T_j \Rightarrow T = T_i W_i + T_j W_j = [W_i \ W_j] \begin{bmatrix} T_i \\ T_j \end{bmatrix} = [W] \{T\}
\]

(44)
Therefore
\[
\frac{\partial T}{\partial t} = \left( 1 - \frac{x}{L_e} \right) \frac{\partial T_i}{\partial t} + \frac{x}{L_e} \frac{\partial T_j}{\partial t} \quad \Rightarrow \quad \frac{\partial T}{\partial t} = W_i \frac{\partial T_i}{\partial t} + W_j \frac{\partial T_j}{\partial t} = [W_i \ W_j] \begin{bmatrix} \frac{\partial T_i}{\partial t} \\ \frac{\partial T_j}{\partial t} \end{bmatrix} = [W] \begin{bmatrix} \frac{\partial T_i}{\partial t} \end{bmatrix}
\] (45)

\[
\frac{\partial T}{\partial x} = \frac{\partial W_i}{\partial x} T_i + \frac{\partial W_j}{\partial x} T_j = \left( -\frac{1}{L_e} \right) T_i + \left( \frac{1}{L_e} \right) T_j = \frac{1}{L_e} (T_j - T_i) \quad \Rightarrow \quad T = -\frac{1}{L_e} \left( \frac{1}{L_e} \right) \begin{bmatrix} T_i \\ T_j \end{bmatrix}
\] (46)

Where:
\[
[B] = \begin{bmatrix} \frac{\partial W_i}{\partial x} \\
\frac{\partial W_j}{\partial x} \end{bmatrix}
\] (47)

After substitution of Eq. (44), (45), (46) and (47) into Eq. (32), we have
\[
\int_0^{L_e} \rho c_p A_{cr} \begin{bmatrix} W_i \\ W_j \end{bmatrix} \frac{\partial T_i}{\partial t} dx + \int_0^{L_e} \left( k + \frac{16\sigma}{3\beta_e} \right) A_{cr} \begin{bmatrix} \frac{\partial W_i}{\partial x} \\ \frac{\partial W_j}{\partial x} \end{bmatrix} \begin{bmatrix} \frac{\partial T_i}{\partial t} \\ \frac{\partial T_j}{\partial t} \end{bmatrix} dx + \int_0^{L_e} h(T) + 4\sigma (T) \varepsilon_0 T_0^2 \begin{bmatrix} W_i \\ W_j \end{bmatrix} \begin{bmatrix} T_i \\ T_j \end{bmatrix} dx
\]

\[
= \int_0^{L_e} (h(T) + 4\sigma (T) \varepsilon_0 T_0^2) PT \begin{bmatrix} W_i \\ W_j \end{bmatrix} dx + \int_0^{L_e} \sigma_m(T) B_e^2 u^2 \begin{bmatrix} W_i \\ W_j \end{bmatrix} \begin{bmatrix} T_i \\ T_j \end{bmatrix} dx
\]

Eq. (48) can be written as
\[
\int_0^{L_e} \rho c_p A_{cr} \begin{bmatrix} W_i \\ W_j \end{bmatrix} \frac{\partial T_i}{\partial t} dx + \int_0^{L_e} \left( k + \frac{16\sigma}{3\beta_e} \right) A_{cr} \begin{bmatrix} \frac{\partial W_i}{\partial x} \\ \frac{\partial W_j}{\partial x} \end{bmatrix} \begin{bmatrix} \frac{\partial T_i}{\partial t} \\ \frac{\partial T_j}{\partial t} \end{bmatrix} dx + \int_0^{L_e} (h(T) + 4\sigma (T) \varepsilon_0 T_0^2) P \begin{bmatrix} W_i \\ W_j \end{bmatrix} \begin{bmatrix} T_i \\ T_j \end{bmatrix} dx
\]

\[
= \int_0^{L_e} (h(T) + 4\sigma (T) \varepsilon_0 T_0^2) PT \begin{bmatrix} W_i \\ W_j \end{bmatrix} dx + \int_0^{L_e} \sigma_m(T) B_e^2 u^2 \begin{bmatrix} W_i \\ W_j \end{bmatrix} \begin{bmatrix} T_i \\ T_j \end{bmatrix} dx
\]

For the i and j nodes of an element, Eq. (49) can be written in a convenient form as
\[
[C_{ij}] \begin{bmatrix} \frac{\partial T_i}{\partial t} \\ \frac{\partial T_j}{\partial t} \end{bmatrix} + [K_{ij}(T)] \begin{bmatrix} T_i \\ T_j \end{bmatrix} = [f_{ij}(T)]
\] (50)

Where
\[
[C_{ij}] = \int_0^{L_e} \rho c_p A_{cr} \begin{bmatrix} W_i \\ W_j \end{bmatrix} \begin{bmatrix} W_i \\ W_j \end{bmatrix} dx
\]

\[
[K_{ij}(T)] = \int_0^{L_e} \left( k + \frac{16\sigma}{3\beta_e} \right) A_{cr} \begin{bmatrix} \frac{\partial W_i}{\partial x} \\ \frac{\partial W_j}{\partial x} \end{bmatrix} \begin{bmatrix} \frac{\partial W_i}{\partial x} \\ \frac{\partial W_j}{\partial x} \end{bmatrix} dx
\] (52)
\[ [f_{ij}(T)] = \int_0^{L_e} \left( h(T) + 4\sigma(T)e_\alpha T_\alpha \right) PT_\alpha [W_i \ W_j]^T + \int_0^{L_e} \sigma_m(T)B_e^2 u^2 T_\alpha [W_i \ W_j]^T \, dx \]

\[ + A_{cr} \left( k + \frac{16\sigma}{3R_\eta} \right) \frac{\partial T}{\partial x} \bigg|_0^{L_e} [W_i \ W_j]^T, \]  

(53)

Alternatively, using the relationships in Eqs. (44) - (46), one can write Eq. (49) in a compact matrix form of as;

\[ \int_0^{L_e} \rho c_p A_{cr} [W]^T \left[ \epsilon \frac{\partial T}{\partial t} \right] \, dx + \int_0^{L_e} \left( k + \frac{16\sigma}{3R_\eta} \right) A_{cr} [B] [B] [T] \, dx 
\]

\[ + \int_0^{L_e} \left( h(T) + 4\sigma(T)e_\alpha T_\alpha \right) P [W]^T [W] [T] \, dx + \int_0^{L_e} \sigma_m(T)B_e^2 u^2 [W]^T [W] [T] \, dx 
\]

\[ = \int_0^{L_e} \left( h(T) + 4\sigma(T)e_\alpha T_\alpha \right) P [W]^T T_\alpha \, dx + \left( A_{cr} \left( k + \frac{16\sigma}{3R_\eta} \right) \frac{\partial T}{\partial x} \right) \bigg|_0^{L_e} [W]^T \]  

(54)

Eq. (54) can be written form as;

\[ [C] \left\{ \frac{\partial T}{\partial t} \right\} + [K(T)][T] = [f(T)] \]  

(55)

Where

\[ [C] = \int_0^{L_e} \rho c_p A [W]^T [W] \, dx \]  

(56)

\[ [K(T)] = \int_0^{L_e} \left( k + \frac{16\sigma}{3R_\eta} \right) A_{cr} [B] [B] [T] \, dx + \int_0^{L_e} \left( h(T) + 4\sigma(T)e_\alpha T_\alpha \right) P [W]^T [W] \, dx 
\]

\[ + \int_0^{L_e} \sigma_m(T)B_e^2 u^2 [W]^T [W] \, dx \]  

(57)

\[ [f(T)] = \int_0^{L_e} \left( h(T) + 4\sigma(T)e_\alpha T_\alpha \right) P [W]^T T_\alpha \, dx + \int_0^{L_e} \sigma_m(T)B_e^2 u^2 [W]^T T_\alpha \, dx 
\]

\[ + A_{cr} \left( k + \frac{16\sigma}{3R_\eta} \right) \frac{\partial T}{\partial x} \bigg|_0^{L_e} [W]^T \]  

(58)

In order to develop the matrix equation for the element, we need to expand Eq. (51) - (54) or the equivalent equations in Eq. (56) – (58). Therefore, the expansions are carried out as follows

\[ [C_{ij}] = \int_0^{L_e} \rho c_p A_{cr} [W_i \ W_j]^T [W_i \ W_j] \, dx = \int_0^{L_e} \rho c_p A_{cr} [W_i W_j W_i W_j] \, dx, \]  

(59)

\[ [K_{ij}(T)] = \int_0^{L_e} \left( k + \frac{16\sigma}{3R_\eta} \right) A_{cr} \left[ \frac{\partial W_i}{\partial x} \frac{\partial W_j}{\partial x} \right] \left[ \frac{\partial W_i}{\partial x} \frac{\partial W_j}{\partial x} \right] \left[ T_i \ T_j \right] \, dx 
\]

\[ + \int_0^{L_e} \left( h(T) + 4\sigma(T)e_\alpha T_\alpha \right) P \left[ W_i W_j W_i W_j \right] \left[ T_i \ T_j \right] \, dx 
\]

\[ + \int_0^{L_e} \sigma_m(T)B_e^2 u^2 \left[ W_i W_j W_i W_j \right] \left[ T_i \ T_j \right] \, dx \]

\[ [f_{ij}(T)] = \int_0^{L_e} \left( h(T) + 4\sigma(T)e_\alpha T_\alpha \right) PT_\alpha \left[ W_i \ W_j \right] \, dx \]  

(61)
\[ + \int_{0}^{L_e} \sigma_m(T) B_0^2 u T_n \left[ \frac{W_i}{W_j} \right] d \Delta x + A_{cr} \left( k + \frac{16\sigma}{3\beta R} \frac{\partial T}{\partial x} \right)_{0}^{L_e} \left[ \frac{W_i}{W_j} \right] \]

On substituting Eq. (43) into Eq. (46) into the above Eqs. (59) - (61), one arrives. For the global capacitance matrix, we have

\[ [C_{ij}] = \int_{0}^{L_e} \rho c_p \left[ \begin{array}{cc}
1 - \frac{x}{L_e} & 1 - \frac{x}{L_e} \\
\frac{x}{L_e} & \left( \frac{x}{L_e} \right)^2 \\
\left( \frac{1}{L_e} \right) \left( \frac{1}{L_e} \right)^2
\end{array} \right] dx \]  

(62)

For the stiffness matrix,

\[ [K_{ij}(T)] = \int_{0}^{L_e} \left( k + \frac{16\sigma}{3\beta R} A_{cr} \right) \left[ \begin{array}{cc}
1 - \frac{x}{L_e} & 1 - \frac{x}{L_e} \\
\frac{x}{L_e} & \left( \frac{x}{L_e} \right)^2 \\
\left( \frac{1}{L_e} \right) \left( \frac{1}{L_e} \right)^2
\end{array} \right] dx + \int_{0}^{L_e} \left( h(T) + 4\sigma(T) e_x T_3^2 \right) \rho \left[ \begin{array}{cc}
1 - \frac{x}{L_e} & 1 - \frac{x}{L_e} \\
\frac{x}{L_e} & \left( \frac{x}{L_e} \right)^2 \\
\left( \frac{1}{L_e} \right) \left( \frac{1}{L_e} \right)^2
\end{array} \right] dx \]  

(63)

For the load vector

\[ [f_i(T)] = \int_{0}^{L_e} \left( h(T) + 4\sigma(T) e_x T_3^2 \right) \rho \left[ \begin{array}{cc}
1 - \frac{x}{L_e} & 1 - \frac{x}{L_e} \\
\frac{x}{L_e} & \left( \frac{x}{L_e} \right)^2 \\
\left( \frac{1}{L_e} \right) \left( \frac{1}{L_e} \right)^2
\end{array} \right] T_n dx + \int_{0}^{L_e} \sigma_m(T) B_0^2 u^2 \left[ \begin{array}{cc}
1 - \frac{x}{L_e} \\
\frac{x}{L_e}
\end{array} \right] T_n dx \]  

(64)

After the integrations, we have the global capacitance matrix, stiffness matrix and the load vector as;

\[ [C_{ij}] = \frac{\rho c_p A L_e}{6} \left[ \begin{array}{cc}21 & 12 \\
6 & 12
\end{array} \right] \]  

(65)

\[ [K_{ij}(T)] = \left[ k + \frac{16\sigma}{3\beta R} A_{cr} \right] \left[ \begin{array}{cc}1 & -11 \\
-11 & 6
\end{array} \right] + \frac{(h(T) + 4\sigma(T) e_x T_3^2) P L_e}{6} \left[ \begin{array}{cc}21 & 12 \\
12 & 21
\end{array} \right] + \frac{\sigma_m(T) B_0^2 u^2 L_2}{6} \left[ \begin{array}{cc}21 & 12 \\
12 & 21
\end{array} \right] \]  

(66)

\[ [f_i(T)] = \frac{(h(T) + 4\sigma(T) e_x T_3^2) P L_e + \sigma_m(T) B_0^2 u^2 L_2}{2} + \left[ k + \frac{16\sigma}{3\beta R} A_{cr} \right] \left[ \begin{array}{cc}\frac{\partial T(0)}{\partial x} & \frac{\partial T(L_e)}{\partial x}
\end{array} \right] \]  

(67)

Substitution Eq. (65) – (67) into Eq. (50), gives the characteristic equation over the space interval \( \Delta x \) as;

\[ \frac{\rho c_p A L_e}{\kappa} \left[ \begin{array}{cc}21 & 12 \\
17 & 12
\end{array} \right] \left[ \frac{\partial T}{\partial x} \right] + \left[ k + \frac{16\sigma}{3\beta R} A_{cr} \right] \left[ \begin{array}{cc}1 & -11 \\
-11 & 6
\end{array} \right] + \frac{(h(T) + 4\sigma(T) e_x T_3^2) P L_e}{\kappa} \left[ \begin{array}{cc}21 & 12 \\
12 & 21
\end{array} \right] \]  

(68)
\[
\begin{align*}
\mathbf{f}_i(T) &= (h(T)P + 4\sigma(T)\varepsilon_{o}T_o^3P + \sigma_m(T)B^2_o u^2) \frac{T_m L_e}{6} \left[ \begin{array}{c}
\frac{1}{4} \\
\frac{1}{2} \end{array} \right] (k + \frac{16\sigma}{3\beta_R}) A_{cr} \left[ \begin{array}{c}
\frac{\partial T(0)}{\partial x} \\
\frac{\partial T(M)}{\partial x} \\
\frac{\partial T(L)}{\partial x}
\end{array} \right] \\
\mathbf{K}_{ij}(T) &= \left[ k + \frac{16\sigma}{3\beta_R} \right] A_{cr} \left[ \begin{array}{ccc}
7 & -8 & 1 \\
-8 & 16 & -8 \\
1 & -8 & 7
\end{array} \right] \\
\mathbf{C}_{ij} &= \rho c_p A_{cr} L_e \left[ \begin{array}{ccc}
8 & 4 & -2 \\
4 & 32 & 4 \\
-2 & 4 & 8
\end{array} \right]
\end{align*}
\]

\[
\frac{\rho c_p A_e L_e}{6} \begin{bmatrix} 8 & 4 & -2 \\ 4 & 32 & 4 \\ 1-2 & 4 & 8 \end{bmatrix} \begin{bmatrix} \frac{\partial T_i}{\partial t} \\ \frac{\partial T_j}{\partial t} \\ \frac{\partial T_k}{\partial t} \end{bmatrix} + \begin{bmatrix} (k + \frac{16\sigma}{3\beta_p}) \mathcal{A}_{cr} \begin{bmatrix} 7 & -8 & 1 \\ -8 & 16 & -8 \\ 1 & -8 & 7 \end{bmatrix} \\
\end{bmatrix} + (h(T)P + 4\sigma(T)e_\theta T_\theta^2P + \sigma_m(T)B_\theta^2u^2) \frac{L_e}{60} \begin{bmatrix} 8 & 4 & -2 \\ 4 & 32 & 4 \\ 1-2 & 4 & 8 \end{bmatrix} \begin{bmatrix} T_i \\ T_j \\ T_k \end{bmatrix}
\]

\[
= (h(T)P + 4\sigma(T)e_\theta T_\theta^2P + \sigma_m(T)B_\theta^2u^2) \frac{T_e L_e}{6} \begin{bmatrix} 1 & 4 \\ 1 & 1 \end{bmatrix} + \begin{bmatrix} \frac{\partial T(0)}{\partial x} \\ \frac{\partial T(M)}{\partial x} \end{bmatrix}
\]

\[\frac{\partial T}{\partial x}
\]

\[\frac{\partial T}{\partial y}
\]

\[\frac{\partial T}{\partial z}
\]

(73)

3.1. Time discretization using the Finite Difference Method (FDM)

The above equation is a general representation of a one-dimensional problem with one linear element. All the terms are included irrespective of the boundary condition. Eq. (50) or (55) is semi-discrete as it is discretized only in space. The differential operator still contains the time-dependent term and it has to be discretized. We now require a method of discretizing the transient terms of the equation. The following subsections give the details of how the transient terms are discretized.

\[
[C] \begin{bmatrix} T_i^{m+1} - T_i^m \\ T_j^{m+1} - T_j^m \\ T_k^{m+1} - T_k^m \end{bmatrix} + [K_i(T)] \begin{bmatrix} \theta T_i^{m+1} + (1 - \theta)T_i^m \\ \theta T_j^{m+1} + (1 - \theta)T_j^m \end{bmatrix} = \begin{bmatrix} \theta f_i^{m+1} + (1 - \theta)f_i^m \\ \theta f_j^{m+1} + (1 - \theta)f_j^m \end{bmatrix}
\]

which can be compactly written as;

\[
[C] \begin{bmatrix} T_i^{m+1} - T_i^m \\ T_j^{m+1} - T_j^m \end{bmatrix} + [K(T)] \begin{bmatrix} \theta T_i^{m+1} + (1 - \theta)T_i^m \\ \theta T_j^{m+1} + (1 - \theta)T_j^m \end{bmatrix} = \begin{bmatrix} \theta f_i^{m+1} + (1 - \theta)f_i^m \\ \theta f_j^{m+1} + (1 - \theta)f_j^m \end{bmatrix}
\]

(74)

Therefore,

\[
[[C] + \theta \Delta t[K(T)]]T^{m+1} = [[C] - (1 - \theta)\Delta t[K(T)]]T^m + \Delta t(\theta f^{m+1} + (1 - \theta)f^m)
\]

(75)

(76)

where, "m" denotes the time level.

Eq. (76) gives the nodal values of temperature at the m + 1, time level. These temperature values are calculated using the m time level values. However, both the m + 1 and m time level values of the forcing vector (f) must be known. By varying the parameter θ, different transient schemes can be constructed, which are shown in Table 4 for varying values of θ. Therefore, for the temporal discretization, two-level θ method has been used for the analysis. This approach varies between explicit and implicit strategies and results in the algebraic systems of nonlinear equations.
It is very difficult to provide explicit solutions to the developed systems of nonlinear equations. Therefore, recourse is made to use an iterative predictor-corrector scheme, based on direct substitution iteration to handle nonlinearity in the present analysis. Based on the name, this scheme is an algorithm that proceeds in two steps, namely; the predictor step and then the corrector step. It calculates a rough approximation of the desired quantity in the predictor step and refines the approximation in the corrector step. This scheme combines the advantages associated with explicit and implicit time schemes and hence provides the stable solution to solve complex nonlinear problems (Lewis and Roberts [51]). The steps are shown as follows:

**Predictor**

\[
\begin{align*}
\left[ [C(T^m)] + \theta \Delta t A(T^m) \right] T^{m+1}_p &= \left[ [C(T^m)] - (1 - \theta) \Delta t A(T^m) \right] T^m + \Delta t \{ \theta B(T^m) f^{m+1} + B(T^m)(1 - \theta) f^m \} \\
\end{align*}
\]  

(77)

**Corrector**

\[
\begin{align*}
\left[ [C(T^p)] + \theta \Delta t A(T^p) \right] T^{m+1}_p &= \left[ [C(T^p)] - (1 - \theta) \Delta t A(T^p) \right] T^m + \Delta t \{ \theta B(T^p) f^{m+1} + B(T^p)(1 - \theta) f^m \} \\
\end{align*}
\]  

(78)

Where \( p = 0, 1, 2, 3 \ldots \) up to convergence

\[
T^p_0 = w T^{m+1}_p + (1 - w) T^m \quad 0 \leq w \leq 1
\]  

(79a)

\[
T^{m+1}_0 = T^{m+1}_p
\]  

(79b)

### 3.2. Time discretization using the Finite Element Method

Alternatively, the temporal term in the transient equation can be discretized by using finite element method to discretize Eq. (76) in the time domain. In Eq. (76), the temperature is now discretized in the time domain as in Fig. (4).

![Time discretization between nth (i) and n+1th (j) time levels](image)

Fig. 5 Time discretization between nth (i) and n+1th (j) time levels

\[
T(t) = N_i(t) T_i(t) + N_j(t) T_j(t) = \begin{bmatrix} N_i(t) & N_j(t) \end{bmatrix} \begin{bmatrix} T_i(t) \\ T_j(t) \end{bmatrix}
\]  

(80)

Following the similar procedure as done previously, we can derive the linear shape functions as

\[
N_i(t) = 1 - \frac{t}{\Delta t}, N_j(t) = \frac{t}{\Delta t}
\]  

(81)

Therefore, the time derivative of the temperature is thus written as
The dimensionless form of the governing equation can be derived for the computer program, which is used to solve the system of differential equations. Although, a few boundary conditions and the temperature at the boundary of the system are considered. The above equation involves the temperature values at the nth boundary of the system.

After the evaluation of $E \frac{E}{\Delta t}$, we have

$$\frac{\partial T(t)}{\partial t} = \frac{\partial N_i(t)}{\partial t} T_i(t) + \frac{\partial N_j(t)}{\partial t} T_j(t) = \left( \frac{1}{\Delta t} \right) T_i(t) + \left( \frac{1}{\Delta t} \right) T_j(t) = \frac{1}{\Delta t} (T_j(t) - T_i(t)) \quad (82)$$

Substituting Eqns. (77) and (79) into Equ. (54) and applying the weighted residual principle (Galerkin method), we obtain for a time interval of $\Delta t$,

$$\int_{\Delta t} \left[ \left[ \frac{N_i(t)}{N_j(t)} \right] [C] \frac{1}{\Delta t} \frac{1}{\Delta t} \left[ T_i(t) \right] + \left[ K(T) \right] \left[ N_i(t) N_j(t) \right] \left[ T_i(t) \right] \right] \left[ \int_{\Delta t} \frac{d}{dt} \left[ f(T) \right] \right] dt \quad (83)$$

After expansion, we have

$$\int_{\Delta t} \left[ \left[ \frac{N_i(t)}{N_j(t)} \right] \left[ \frac{1}{\Delta t} \frac{1}{\Delta t} \left[ T_i(t) \right] + \left[ K(T) \right] \left[ N_i(t) N_j(t) \right] \left[ T_i(t) \right] \right] \right] \left[ \int_{\Delta t} \frac{d}{dt} \left[ f(T) \right] \right] dt \quad (84)$$

Substituting Eq. (78) into Equ. (81)

$$\int_{\Delta t} \left[ \left[ \frac{N_i(t)}{N_j(t)} \right] \left[ \frac{1}{\Delta t} \frac{1}{\Delta t} \left[ T_i(t) \right] + \left[ K(T) \right] \left[ N_i(t) N_j(t) \right] \left[ T_i(t) \right] \right] \right] \left[ \int_{\Delta t} \frac{d}{dt} \left[ f(T) \right] \right] dt \quad (85)$$

Again, after expansion of Eq. (85), one arrives at

$$\int_{\Delta t} \left[ \left[ \frac{N_i(t)}{N_j(t)} \right] \left[ \frac{1}{\Delta t} \frac{1}{\Delta t} \left[ T_i(t) \right] + \left[ K(T) \right] \left[ N_i(t) N_j(t) \right] \left[ T_i(t) \right] \right] \right] \left[ \int_{\Delta t} \frac{d}{dt} \left[ f(T) \right] \right] dt \quad (86)$$

After the evaluation of Eq. (86), we obtained the characteristic equation over the time interval $\Delta t$ as

$$\frac{1}{2\Delta t} \left[ \left[ C \right] \left[ \frac{1}{\Delta t} \frac{1}{\Delta t} \left[ T_i(t) \right] + \left[ K(T) \right] \left[ \frac{1}{\Delta t} \frac{2}{\Delta t} \left[ T_i(t) \right] + \left[ \frac{1}{\Delta t} \frac{1}{\Delta t} \left[ f_i \right] \right] \right] \right] \right] = \left[ \frac{1}{2\Delta t} \frac{1}{\Delta t} \left[ f_i \right] \right] \quad (87)$$

The above equation involves the temperature values at the $m$th and $(m + 1)$th level. The quadratic variation of temperature with respect to time shown in Eq. (73) can be treated in a similar fashion.

The boundary conditions and the temperature-dependent parameters are incorporated in the computer program used to solve the system of differential equations. Although, a dimensionless form of the governing equation can be derived for the computer program,
so that the handling of physical quantities is simplified. It should be noted that the thermal properties are evaluated directly in each time step from the nodal temperatures. This eliminates any iteration within each time step for the evaluations of the temperature-dependent parameters.

The element equation/matrix has been derived as shown in the previous equations. It should be noted that the whole domain was divided into a set of 50 line elements. Assembling all the elements equation/matrices, a global matrix or a system of equations was obtained. After applying the boundary conditions, the resulting systems of equations is solved numerically.

The convergence criterion of the numerical solution along with error estimation has been set to

$$\sum_{i}^{N} |\phi_i - \phi_{i-1}| \leq 10^{-4}$$

where $\phi$ is the general dependent variable $T$ and $i$ is the number of iterations.

It should be noted that a steady state is attained when $\frac{\partial T}{\partial t} = 0$ or $t \rightarrow \infty$.

4. Results and Discussion

For the computational domain, numerical solutions are computed and the necessary convergence of the results is achieved with the desired degree of accuracy. Using the numerical solutions, parametric studies are carried out. Also, in order to define the validity of the results of thermal analysis of fin with assumed insulated tip and that of convective tip, effects of the fin tip conditions on the transient thermal response are investigated. The results with the discussion are illustrated through the Figs. 6-18 and Tables 5-6 to substantiate the applicability of the present analysis.

4.1 Verification of results

In order to verify the accuracy of the present numerical method, the numerical results are compared with results obtained by exact analytical method for the linear equation in Eq. (14) as shown in Table 5 and Fig. 6. It is inferred from the figure that there are excellent
agreements between the FEM results and the analytical results, which testifies to the validity of the FEM code. This validation boosts the confidence in the numerical outcomes of the present study. Moreover, it is observed that in the same domain by increasing the polynomial degree of approximation or the number of nodes in an element, one can achieve the desired accuracy with less DOF.

Table 5 shows the comparison of the results obtained by exact analytical and finite element methods for a conductive-convective fin with constant thermal and physical properties of fin having negligible radiation and magnetic field effects. Very good agreements are found between the exact analytical and finite element solutions. The average percentage error of the numerical solution is 0.133 %.

Fig. 6 Comparison of results

Fig. 7(a) Fin temperature profile at different location (convective tip)

Fig. 7(b) Effects of multi-boiling parameter on the fin temperature distribution

Fig. 8 Fin temperature profile at different location (insulated tip)
Figs. 7 and 8 depict temperature-time history at different four points (0.025 m, 0.050m, 0.075 m and 0.100 m) of the convective-radiative fin with convective and insulated tips, respectively while Fig. 9 and 10 show the temperature profiles of the fin at difference times. The temperature histories at the four points decrease at a faster rate initially, slows down thereafter and finally tending to reach a constant value showing to be near to steady state. Also, a marginal or slightly higher temperature differences are notice between the convective and insulated tip. However, this temperature differences become appreciable as the length of the fin increases and heat is transferred within a short period of time. It could be inferred form the figures and the preceding discussion that for a short fin that undergo heat transfer for a prolonged period of time, adiabatic/insulted condition at the tip can be assumed without any significant loss in accuracy.
It has been established that the criterion and errors due to one-dimensional heat transfer analysis is that fin base thickness Biot number should be much smaller than unity (precisely, $Bi < 0.1$). To this end, a one-dimensional analysis has been carried out and simulated within $0 < Bi < 0.1$. In this case the error made in the determination of the rate of
heat transfer from the fin to the fluid surrounding it is less than 1% [67, 68]. However, when the Biot number is greater than 0.1 (Bi > 0.1), two-dimensional analysis of the fin is recommended as one-dimensional analysis predicts unreliable results for such limit.

Figs. 11 and 12 show the effects of Biot number (conduction-convection parameter) on the temperature distribution in the fin with convective and insulated tips, respectively. From the figures, it is shown that as the Biot number increases, the rate of heat transfer through the fin increases as the temperature in the fin drops faster (becomes steeper reflecting high base heat flow rates) as depicted in the figures.

Effects of heat transfer coefficient on the temperature distribution in the fin is shown in Fig.13. It is shown that the temperature profiles for the various heat transfer coefficient coincide initially but part away as we move towards the tip of the fin. This is due to the fact that coefficient of heat transfer coefficient is a factor/multiplier of the temperature difference between the fin surface and surrounding medium (\(T-T_\infty\)). It should be noted that the temperature difference between the fin surface and the surrounding decreases as we move away from the fin base to the fin tip even despite the increase in the heat transfer coefficient increases.

It should be noted that for the fin with heat transfer coefficient which varies according to power-law, the hypothetical boundary condition (that is, insulation) at the tip of the fin is taken into account. If the tip is not assumed to be insulated, then the problem becomes overdetermined [68]. This boundary condition is realized for sufficiently long fins. Also, it should be stated that the assumption that the heat transfer coefficient is constant yields incorrect.

Fig. 14 presents the impact of emissivity on the temperature distribution. The temperature of the fin decreases with increase of emissivity value. This is because of increase of emissive heat by radiation from the fin surface especially when the distance from the base increase. Therefore, heat transfer rate increases as the emissivity increases. The radiative heat transfer can be neglected if the base temperature of the fin is low and the emissivity of the fin surface is near zero. The important things in fins surface must be emissive because of high emissivity give a great amount of heat radiation transfer from the fin [38]. It is also established that by increasing the generation-conduction parameter and radiation-conduction parameter, the fin temperature will increase [71].

Fig.15 shows that effects of magnetic parameter, Hartman number on the temperature distribution in the porous fin. The figure depicts that the induced magnetic field in the fin can improve heat transfer through the fin. It is shown that increase in magnetic field on the fin increase the rate of heat transfer from the fin and consequently improve the efficiency of the fin. Fig. 16 shows the effect thermal conductivity of the fin materials on the thermal response of the fin. It could be inferred from the figure that more heat is transferred from fin made of copper material than the fins made of stainless steel and aluminum materials.

Effects of the thermal and geometric parameters on the temperature profile of the fin are shown in Fig. 17 while Fig. 18 shows the influence of thermo-geometric parameter \((M=(hP/kA)^{0.5})\) on the thermal stability of the fin. It was established that the value of \(M\) produces physically unsound behavior for larger values of the thermo-geometric parameter. It is shown that for growing values of the thermo-geometric parameter the temperature tends to negative values at the tip of the fin which shows thermal instability, contradicting the assumption of Eq. 9. Following the assumptions made regarding the numerical solution of the problem, it was realized that these solutions are not only physically unsound but also point toward thermal instability. Therefore, in order for the solution to be physically sound the fin thermo-geometric parameter \(M_{\text{max}}\) must not exceed a specific value. By extension, in order to ensure stability and avoid numerical diffusion of
the solution by the Galerkin finite element method, the thermo-geometric parameter, $M$ must not exceed a certain value.

It is established from the results in the Tables 6a and 6b, that for a relatively short fin operating for prolonged periods of time, the results indicate that the adiabatic/hypothetical condition (or negligible heat transfer) at the tip can be assumed without any significant loss in accuracy or equality as compared to the convective boundary at the tip. This is because, for the relatively short fin operating under a steady state, the assumption of insulated tip (or negligible heat transfer at the tip) predicted almost the same results as there is no significant difference between the results of the assumed insulated tip and convective tip. Moreover, for a sharp ended fin, its performance is the same as insulated tip fin. Under such scenario, the fin tip heat convection analysis becomes meaningless due to the infinitesimally small dissipating area. However, for a long cooling fin of finite length operating in a transient state, especially for short period of time, the assumption of insulated tip produces significant different results as compared to the results of the convective tip (Table 6b). It is therefore implied that if it is assumed that no heat transfer takes place at the fin tip, the results obtained for some ranges of thermal and geometric parameters indicate that the determination of temperature distribution and the rate of heat transfer from the fin to its surroundings includes a fairly large error for some conditions which are important for practical applications. Therefore, for transient thermal studies of fins, the assumption of no heat transfer takes place at the fin tip should be taken with caution in thermal analysis of a long cooling fin of finite length operating within a short period of time such as the fin operating under picosecond or nanosecond. Also, such an assumption should not be made when the convective heat transfer coefficient at the tip of the fin is very high or the thermal conductivity of the fin material is very low. It was established that the difference between the results of the insulated tip and convective tip increases as the tip Biot number is increased. In fact, the percentage error of the difference between the results of the insulated tip and convective tip for a very high value of heat transfer coefficient could be as high as 20 % [72].
5. Conclusion

In this work, transient thermal behavior of convective-radiative cooling fin with convective tip and subjected to magnetic field have been analyzed using Galerkin finite element method. The numerical solutions are verified by the exact solution developed using Laplace transform. The study revealed that increase in Biot number, convective, radiative and magnetic parameters increase the rate of heat transfer from the fin and consequently, improved the efficiency of the fin. Also, it was established that for a relatively short fin operating for prolonged periods of time or steady state, the adiabatic/hypothetical condition (or negligible heat transfer) at the tip can be assumed without any significant loss in accuracy or equality as compared to the convective condition at the tip. However, for a long cooling fin of finite length operating in a transient state, especially for short period of time, the assumption of insulated tip produces significant different results as compared to the results of the convective tip. Therefore, for transient thermal studies of fins, the assumption that no heat transfer takes place at the fin tip should be taken with caution for a long cooling fin of finite length operating within a relatively short period of time. It is hope that the present study will enhance the understanding of thermal response of solid fin under various factors and especially of practical significance in chemical and nuclear engineering.

Nomenclature

- $A$: cross sectional area of the fins, m$^2$
- $B_0$: Magnetic field intensity (T)
- $Bi$: Biot number
- $C_p$: specific heat (J kg$^{-1}$ K$^{-1}$)
- $H$: Heat transfer coefficient (J m$^{-2}$ K$^{-1}$)
- $h_b$: heat transfer coefficient at the base of the fin, (W m$^{-2}$ K$^{-1}$)
- $J$: Total current intensity (A)
- $J_c$: Conduction current intensity (A)
- $k$: thermal conductivity of the fin material, (W m$^{-1}$ K$^{-1}$)
- $k_b$: thermal conductivity of the fin material at the base, (W m$^{-1}$ K$^{-1}$)
- $L$: Length of the fin (m)
- $M$: dimensionless thermo-geometric parameter
- $P$: perimeter of the fin (m)
- $q$: heat transfer rate W
- $t$: time
- $T$: fin temperature (K)
- $T_\infty$: ambient temperature, K
- $T_b$: Temperature at the base of the fin, K
- $w$: width of the fin
- $x$: axial length measured from fin base (m)
- $w$: width of the fin
