Abstract Use of flax as thermal insulation on a cylindrical calorimeter is proposed in this study. Flax used has medium diffusivity $\alpha = 8.10^{-7}\, \text{m}^2\cdot\text{s}^{-1}$ and average thermal conductivity $\lambda = 0.037\, \text{W} \cdot \text{m}^{-1} \cdot \text{K}^{-1}$. Thermal behavior of flax material is highlighted from the study of temperature and heat flow density curves. Spectroscopic study from Bode diagrams and Nyquist representation of thermal impedance and its phase showed the quality of thermal insulation. Thermoelectric parameters such as series resistance and shunt resistor have made it possible to characterize the material.

Keywords: Flax - Temperature - Series resistance - Shunt resistance

1. Introduction

Artificial or synthetic insulation [1, 2] is a threat to the environment unlike natural insulation that is biodegradable and renewable. Studies on heat transfer have shown that these natural insulators (tow, kapok, sawdust ...) have a very good thermal insulation property [3, 4]. Studies on different models [5, 6, 7] have shown the quality of some thermal insulators such as tow or kapok.

In this study, we characterize the thermal behavior of flax over a hollow aluminum cylinder filled with a warm homogeneous liquid solution. We follow the thermal inertia of the filasse material from the study of the evolution curves of the temperature and the density of heat flow in dynamic frequency regime. Calorimetric times or periods of measurement are relatively short which corresponds to relatively high excitatory pulsations (high frequencies). We thus analyze the Bode diagrams and the Nyquist representations by showing the behavior of the high-frequency material.

2. Theory

2.1. Scheme of study device

Different outer surfaces of calorimeter are considered subject to same external climatic constraints. Calorimeter is considered a closed system. Initial temperature of the fluid in calorimetric vessel is everywhere same.

2.2. Mathematical model

We consider that system is in cylindrical symmetry. Equation of heat (1) is obtained by considering that material does not contain an internal source of heat.

$$\frac{\partial^2 T}{\partial r^2} + \frac{1}{r} \frac{\partial T}{\partial r} + \frac{\partial^2 T}{\partial z^2} - \frac{1}{\alpha} \frac{\partial T}{\partial t} = 0$$

(1)

$$\alpha = \frac{\lambda}{\rho \cdot C}$$

(2)
\( \lambda \) = thermal conductivity
\( \rho \) = density of the material
\( C \) = massic heat

### Figure 1: Schematic of calorimeter

- **\( T_1 \)**: Temperature inside solution.
- **\( T_2 \)**: Ambient temperature
- **\( T_i \)**: Initial temperature of flax
- **\( R_1 \)**: Inner radius of flax layer
- **\( R_2 \)**: Outer radius of flax layer
- **\( e_r \)**: Thickness of insulation in radial direction
- **\( e_z \)**: Thickness of insulation along z axis

Solution of equation (1) in dynamic frequency regime is given by equation (3):

\[
T(r, z, \omega, t) = \sum_{j=1}^{\infty} \left[ A_j \sinh(\beta_j z) + B_j \cosh(\beta_j z) \right] J_0(\mu_j r) e^{i\omega t} + T_i
\]

With

\[
J_0(\mu_j r) = \sum_{m=1}^{\infty} \frac{(-1)^m (\mu_j r)^{2m}}{4^m m! m!}
\]

We obtain expressions of components \( A_j \) and \( B_j \) from equations (5) and (6). Equations (7) and (8) make it possible to obtain eigenvalues which are determined graphically from transcendental equations (9) and (11).
\[ \lambda \mu_j = \frac{J_0(\mu_j R_2) \left( -T_{01} + T_i e^{-i\omega t} \right) + J_0(\mu_j R_1) \left( T_{02} - T_i e^{-i\omega t} \right)}{h_1, h_2, \mu_j R_2} - \frac{J_0(\mu_j R_2) \left( -T_{01} + T_i e^{-i\omega t} \right) + h_2 J_1(\mu_j R_1) \left( -T_{02} + T_i e^{-i\omega t} \right)}{h_1 J_1(\mu_j R_2)} \] (9)

we pose:
\[ n_j = e.\mu_j \] (10)

\[ g(n_j) = \frac{n_j R_2}{h_1, h_2, e} \] and \[ f(n_j) = \frac{n_j R_2}{h_1 J_1(\mu_j R_1)} \]

We graphically determine the eigenvalues \( n_j \) and \( \mu_j \).

Figure 2: Graphical determination of eigenvalues \( \mu_j \)

\( h_1 = 60 \text{ (W/m}^2\text{.K)} \); \( h_2 = 1 \text{ (W/m}^2\text{.K)} \); \( \omega = 0.001 \text{ rad.s}^{-1} \).

Table 1: Eigenvalues

Expression (12) gives the density of heat flow through flax material.

\[ \phi(r, z, \omega, t) = \left\{ \sum_{j=1}^{\infty} \left[ e^{i\omega t} \mu_j J_1(\mu_j r) \left( A_j \sinh(\beta_j z) + B_j \cosh(\beta_j z) \right) \right] \right\} \] (12)

By analogy with Ohm’s law, we write:

\[ \Delta T(r, z, \omega, t) = T(r, 0, \omega, t) - T(r, z, \omega, t) = \sum_{j=1}^{\infty} B_j \left[ 1 - \cosh(\beta_j z) \right] - A_j \sinh(\beta_j z) \] (13)

Relation (14) expresses temperature variation inside material.

\[ T(r, 0, \omega, t) - T(r, z, \omega, t) = \sum_{j=1}^{\infty} B_j \left[ 1 - \cosh(\beta_j z) \right] - A_j \sinh(\beta_j z) \] (14)

Taking into account expression (13), expression (15) of thermal impedance of flax is obtained.
\[
Z_{th}(r, z, \omega, t) = \sum_{j=1}^{\infty} \left[ B_j (1 - \cosh(\beta_j z)) - A_j \sinh(\beta_j z) \right] J_0(\mu_j r) e^{i\omega t} / \phi(r, z, \omega, t)
\] 

(15)

3. Results

3.1. Evolution of temperature and density of heat flux in flax

Figures (3) and (4) respectively show changes in temperature and heat flow density on the base (or lid) of the calorimeter. Figures (5) and (6) show changes in temperature and heat flow density on side wall of the calorimeter. In these different evolutions, we highlight influence of excitatory pulsation.

Figure 3: Evolution of temperature on cover of calorimeter.

\[ r = 0.055 \text{ m}; \; h_1Z = 25 \text{ W/ (m}^2\cdot\text{K}); \; h_2Z = 0.05 \text{ W/ (m}^2\cdot\text{K}). \]

Figure 4: Evolution of heat flow density on calorimeter cover.

\[ r = 0.055 \text{ m}; \; h_1Z = 25 \text{ W/ (m}^2\cdot\text{K}); \; h_2Z = 0.05 \text{ W/ (m}^2\cdot\text{K}). \]

Figure 5: Evolution of temperature on lateral face of calorimeter.

\[ z = 0.002 \text{ m}; \; h_1Z = 25 \text{ W/ (m}^2\cdot\text{K}); \; h_2Z = 0.05 \text{ W/ (m}^2\cdot\text{K}). \]

Figure 6: Evolution of heat flow density on side face of calorimeter.

\[ z = 0.002 \text{ m}; \; h_1Z = 25 \text{ W/ (m}^2\cdot\text{K}); \; h_2Z = 0.05 \text{ W/ (m}^2\cdot\text{K}). \]

Evolution of temperature curves, Figures (3) and (5), shows existence of a considerable contact resistance \( R_C \) between the aluminum assumed at the temperature of solution \( (T_i = 90^\circ\text{C}) \) et and flax at temperature \( T_F \approx 40^\circ\text{C} \).

\[ T_F - T_i = R_C \cdot \phi \]

Flax material thus has a good thermal inertia to these excitatory pulsations and can be well insulation.
pulsations corresponding to relatively short periods of measurement give a better behavior of the thermal insulation.

### 3.2. Bode diagrams and Nyquist representations

Figures (7) and (8) respectively represent Bode diagrams of impedance and its phase for different values of depth of flax material. Figure 9 shows evolution of imaginary part of thermal impedance as a function of its real part. Phenomena are highlighted for different values of the depth of flax.

Figure 10: Evolution of resistance as function to thickness of flax material

Figure 11: Equivalent electrical model of inductive phenomena of flax

For high excitation pulsations ($\omega > 10^{-3}\text{rad.s}^{-1}$), thermal impedance is relatively high (Figure 7), which allows a significant retention of heat. This gives the material thermal stability. Table 2 gives some values of thermal impedance module.

Phase of impedance remains positive and has a maximum for $\omega \approx 10^{-3}\text{rad.s}^{-1}$ (figure 8), This behavior is translated into electricity by inductive phenomena (Figure 11) corresponding to a return of heat to the solution in calorimeter. This phenomenon leads to an increase in calorimeter's performance.

Values of resistances given in Table 3 are obtained from the exploitation of Nyquist representations (Figure 9). Figure 10 gives an evolution of resistances as a function of depth. Phenomena of thermal insulation increase linearly with the thickness of the thermal insulation.

4. Conclusion

Study shows that use of flax as a thermal insulator has considerable efficiency due to the contact resistance between aluminum and flax.

Spectroscopy of thermal impedance shows that for high excitatory pulsations we have an important module of thermal impedance.

Thermal resistance characterizes the phenomena of conduction inside the material. Quality of thermal insulator is all more important as thermal resistance is important. Thermal resistance varies linearly with thermal impedance.
