ABSTRACT

*A systematic field study was conducted in crop fields such as food crops, pulses, vegetable crops, oil crops and commercial crops at Visakhapatnam District. A total of 120 weed species belonging to 40 families were carefully studied and recorded. The weed species were grouped as sedges, grasses and broad leaved weeds. The weed species belonging to the family Asteraceae (12 species) and Fabaceae (12 species) were more dominant followed by Euphorbiaceae (11 species), Amaranthaceae (10 species) and Poaceae (7 species), respectively. The species of *Cyperus rotundus*, *Cyperus difformis*, *Cyperus iria*, *Cyperus diffusus*, *Echinochloa colona* and *Echinochloa crusgalli* were recorded as more common and dominant weeds in all cereals crops and broad leaved weeds belonging to Asteraceae, Fabaceae, Euphorbiaceae and Amaranthaceae were recorded in vegetable and other field crops.*

Keywords: Bio-control, crop fields, *Cyperus rotundus* L, weed infestation, weed management.

Weeds are the oldest problem in agriculture since about 10000 B.C. and have represented one of the main limiting factors in profitable crop production (Avery, 1997). They are the most complex and serious problems in natural resource management. Weeds cause significant losses each year in the agriculture, forestry, aquaculture, water supply and a host of other human enterprises. They also affect the health and quality of life of people all over the world by causing allergies and other health hazards (Handerson and Anderson, 1996). Apart from quantitative losses caused by weeds due to competition for water, light, space, nutrients and to the antagonism (parasitism and allelopathy) they also cause qualitative indirect damage due to unitary seed reduction, contamination of seeds slowing of tillage and harvesting practices (Anderson, 1983; Asthon and Monaco, 1991).

A weed is a plant growing where it is not desired (Klingman and Noordhoff, 1961). Weeds are very common, dominant and wide spread in the crop fields. Weed interference is one of the most important factors to decrease the yields of all crops. Weeds are undesirable on account of their competitive and allelopathic behaviour and providing habitats for harmful organisms (Zaman *et al.*, 2011). Weeds present in crop field that compete with crop plants for light, moisture and other essential nutrients, resulting reduce quality and yield of crops and increase the cost of production (Samad *et al.*, 2008). These unwanted, unuseful, often prolific and persistent, competitive, harmful, even poisonous plants that are known as weed, interfere with agricultural operations, increase labour cost, reduce yield and detract from the comfort of life (Crafts and Robbins, 1962).

Email : mycology.au@gmail.com

Weed is a plant which is judged by man to be not of use and undesirable at a place where it flourishes (Patil *et al.*, 2010). The unwanted plants which are growing in crop fields are competing with the crop plants have a short vegetative phase with high reproductive potential. Weed-crop competition is critical in obtaining crop yields because of greater competitive ability of weeds than the crops. Weeds deplete large quantities of mineral nutrients and moisture more efficiently than the crop plants and thrive better over the crops in drought conditions. Weeds have higher contents of nutrients than crop plants; they grow faster and absorb nutrients more efficiently and thus limiting the availability of the same to crop plants (Prayaga Murty and Venkaiah, 2011). Weeds not only compete with crop plants for nutrients, soil moisture, space and sunlight but also serve as an alternative hosts for several insect pest and diseases. Wider spacing, frequent irrigations and liberal use of manures and fertilizers provide favourable conditions for an early start of weeds (Mukherjee *et al.*, 2012).

Weeds are classified into three broad groups based on lifespan: annuals, biennials and perennials. In each group there are both broad leaf weeds and grasses (Rao, 2000). Competition between crops and weeds is maximum when available resources for crop growth become limiting. Competition between crops and weeds is most severe when the competing plants have similar vegetative habits and demands upon resources (Rao, 2000). The degree of weed competition is determined by the weed species infesting the area, density of infestation and duration of infestation. These weeds effectively compete with the crop for nutrients, water, and space reduce the yield ranging from 12 to 51 % (Rao and Singh, 1997; Mukharjee and

Singh, 2005; Halder and Patra, 2007). Weed flora and its composition in a crop is influenced by the type of cultivation, spacing, time or season of cultivation, soil type, soil PH, climatic conditions such as rainfall, temperature, cultivation practices like irrigation, tillage systems, application of fertilizer and weed management (Kiran and Rao, 2013).

Weed infestation is one of major constraints affecting the production which is the most important for each crop. Although weeds have been eradicated using various cultural practices. Commonly used weed control strategies are water management, hand weeding, mechanical weeding and chemical herbicides. Water management can control certain weed species in irrigated lowland. Hand weeding is time-consuming and is becoming expensive, while the use of mechanical weeders is known to reduce yields. Chemical herbicides, on the other hand, not only are becoming more expensive, but also contribute to environmental pollution. Continuous use of chemical herbicides can result in the development of herbicide-tolerant weed populations (Bayot *et al.*, 1994).

The manual and mechanical methods of weed control, besides being less effective, are costly and time consuming. Mechanical weeding was partially effective due to non-removal of weeds in intra-rows (Satyanarayana *et al.*, 2013). Several pre-emergence herbicides like butachlor, thiobencarb, pendimethalin, oxyfluorfen and nitrofen either alone or in combination with hand weeding provide a fair degree of weed control. But use of same group of herbicide with similar mode of action over the period of time on a same piece of land leads to imbalance in weed flora, environmental contamination and development of resistance in weeds (Survase *et al.*, 2013). The development of herbicide resistance in weeds is an example of evolution in plant species as a consequence of environmental as well as cultural changes brought about by man (Bhowmik, 2010).

Biological weed control involves using living organisms, such as insects, nematodes, bacteria, or fungi, to reduce weed populations. Biological control of weeds using plant pathogens is a practical and environmentally sound method of weed management. A variety of herbaceous, woody, climbing, aquatic, and parasitic weeds have been shown to be capable of being controlled by plant pathogens (Charudattan, 1991). The study on weed infestation may helpful to agronomists and farmers for the development of weed control methods. The aim of the research is to identify the frequency of invasive weed flora for the effective

weeding and weed eradication seasonally through the mechanical, cultural and chemical means. Use of biological control methods in field crops is being considered, but still not much in use.

MATERIALS AND METHODS

Visakhapatnam District is one of the North Eastern Coastal districts of Andhra Pradesh and it lies between 17° - 15' and 18°-32' Northern latitude and 18° - 54' and 83° - 30' in Eastern longitude. It is bounded on the North partly by the Orissa State and partly by Vizianagaram District, on the South by East Godavari District, on the West by Orissa State and on the East by Bay of Bengal. Agriculture is the main stay of nearly 70% of the households. Rice is a staple food of the people and Paddy is therefore the principal food crop of the district followed by Ragi, Bajra and Jowar and Cash crops such as Sugarcane, Groundnut, Sesamum and Chillies are important. The rest of the cultivated area is covered under dry crops depending upon the vagaries of the monsoon. The District receives annual normal rainfall of 1202 mm. Agency and inland Mandals receive larger rainfall from the South West Monsoon, while Coastal Mandals get similarly larger rainfall from North-East monsoon. Red Loamy soils predominate with coverage of 69.9% of the villages of the district and Sandy loamy soils come next with 19.2% village's coverage.

The exploration of the area under study includes the planned field trips to various study sites (crop fields) for weed observation, classification and collection. The random sampling method was adopted for this study to note down the presence of weed species among the crop fields. Each field trip includes 5-10 days covering a particular area, during the *kharif* season. Fields were surveyed at three to five weeks after planting. The study includes different agricultural crops classified as food crops, pulses, vegetable crops, oil crops and commercial crops in various agricultural regions of Vishakhapatnam District (Table 1, 2). All the weeds encountered in the field sites of the crop fields were carefully collected and identified during the *kharif* season (July - October 2013).

After completing the weed collection from the crop fields, the weed plants were correctly identified by the help of floras, monographs and other relevant literature and consequently the correct scientific and common names were provided to each plant. Each plant was critically studied and identified using the 'Flora of British India' (Hooker, 1872-1897); 'Flora of Presidency of Madras' (Gamble and Fischer, 1915-

RESULTS AND DISCUSSION

The field crops classified as food crops, pulses, vegetable crops, oil crops and commercial crops in various agricultural regions of Vishakhapatnam District were heavily infested with numerous weed species. The weed infestation was carefully studied by random sampling method and certain rank was allotted to each weed depending on their frequency in study area. A total of 120 weed species belonging to 40 families were carefully studied and recorded (Table 3). The weed infestation was affected by the irrigation or water resources, agricultural practises and climatic conditions. The weed species belonging to the family Asteraceae (12 species) and Fabaceae (12 species) were more dominant followed by Euphorbiaceae (11 species), Amaranthaceae (10 species) and Poaceae (7) respectively. The genera *Cyperus* was most dominant weed among all the weed plants and the species of *Cyperus rotundus*, *Cyperus difformis*, *Cyperus iria* and *Cyperus diffusus* were recorded as more common and dominant weeds in cereals crops such as paddy, maize, jowar and the plantation crop sugarcane and all vegetable crops. The weed species of *Echinochloa colona*, *Echinochloa crusgalli*, *Cynodon dactylon*, *Chloris barbata* and *Digitaria ciliaris* were the common sedges of agricultural crops of study area.

The crop plants were heavily infested with broad leaved weed plants during pre monsoon, monsoon and post monsoon seasons. The weed species belonging to the family Asteraceae, Euphorbiaceae and Amaranthaceae were more common in all vegetable crops, pulses and other crops. The species of *Physalis minima*, *Pedaliium murex*, *Chrozophora rottleri*, *Argemone mexicana*, *Boerhavia diffusa*, *Ruellia tuberosa*, *Trianthema portulacastrum*, *Portulaca oleracea*, *Sphaeranthus indicus*, *Solanum anguivi*, *Tribulus terrestris*, *Tridax procumbens*, *Ipomoea pestigridis*, *Evolvulus alsinoides*, *Marsilia quadrifolia*, *Ageratum conyzoides*, *Cleome viscosa*, *Cleome chelidoni*, *Clitoria ternatea*, *Digera muricata*, *Eclipta prostrate*, *Borreria hispida*, *Phyla nodiflora*, *Parthenium hysterophorus*, *Tephrosia villosa*, *Tephrosia purpurea*, *Aerva lanata*, *Crotalaria verrucosa*, *Mimosa pudica*, *Alternanthera sessilis* and *Xanthium strumarium* were identified and recorded as the common broad leaved weeds of agricultural fields.

The weed infestation in crop fields was affected by seasonal variations, type of crop, type of soil, availability of nutrients and water resources. The habitat, the life span and the seed germination of weed plants were playing the vital role in weed infestation. Hence the knowledge of weed flora of agricultural crops became very crucial since the last few years to manage these unwanted plants. Nowadays the data on weed infestation of crop fields is very important to plant breeders, farmers and agronomist for the control of weed plants which are treated as *energy drains* of field crops.

Numerous plant species are considered as weeds in agronomic cropping systems due to their harmful effects in agricultural fields. Weeds have many attributes undesirable to crop producers, not the least being the ability to reduce crop yields through competition for resources such as sunlight, water, nutrients, and space. Weeds also may harbor insects and provide a host for certain plant pathogens. Eliminating or reducing the deleterious effects of weeds on agronomic crops is the ultimate goal of weed management. Successful weed management requires identifying relevant species and understanding their biological characteristics so that management can be tailored to the weeds present in individual fields.

In modern agriculture system the effective methods for weed management through various methods are indispensable for high yield of a particular crop. Besides the harmful effects the Effective management of weed biomass can have a beneficial effect on soil fertility through the addition of organic matter and plant nutrients, and improvement in soil condition (Munda *et al.*, 2006; Singh, 2003; Sidhu and Beri 1989; Srivastava *et al.*, 1988). The supplementary or complementary use of these on farm weed biomass besides improving soil physical, chemical and biological properties, also improve fertilizer use efficiency (Bera and Ghosh., 2013). The weeds can be checked by adopting various methods like eco-physical, biological, chemical and recently through combining direct and indirect approach i.e. integrated weed management (Kundu *et al.*, 2009).

ACKNOWLEDGMENT

The authors were grateful to *University Grants Commission (UGC)*, New Delhi, India for the finance support under UGC-SAP-CAS-I project in the Department of Botany, Centre of Advanced Study, Andhra University, Visakhapatnam. The authors were very thankful to the farmers of study area for their

valuable information on the local names of crops and weed species and the effects of harmful weeds in crop fields.
