ABSTRACT

One hundred and ten accession of sunflower germplasm were characterized on the basis of qualitative trait and were evaluated for yield and yield components to study the variability for different quantitative traits. Highest genotypic and phenotypic coefficients of variation were recorded for seed yield plant¹ (56.5% and 57.0%) and 100-seed weight (25.6% and 27.7%) respectively. High heritability coupled with high genetic advance over mean were recorded for seed yield plant¹ (98.1% and 115.3%) and number of leaves plant¹ (93.9%, 38.2%) followed by leaf lamina length, leaf lamina width, plant height, 100-seed weight, petiole length, and head diameter. Qualitative traits also showed wide variation among the accessions.

Keywords: Characterisation, genetic variability, Helianthus annuus

Sunflower as one of the important edible oilseed crops in the world is spreading to diverse agroproduction situations and thus necessitates development of more productive hybrids with diverse duration. There is a great scope to increase the production and productivity of sunflower. Das et al (2009) Categorised the sunflower growers into three groups namely resource rich, resource moderate and resource poor depending upon the problems faud by themselves. The nature and magnitude of variability present in a crop has significant impact on the success of plant breeding. Furthermore, the assessment of heritable and non-heritable components of variability and characterisation of germplasm bears immense value in the choice of suitable breeding lines. Hence, the present study was conducted to estimate the amount of genetic variability, heritability and genetic advance over mean for yield and its components and to characterize the different germplasm accessions based on qualitative characters.

MATERIALS AND METHODS

The present study comprised 107 germplasm of sunflower and three checks viz., LS-11, LSF-8 and Modern. The experiment was conducted at Oilseed Research Station, Latur, Maharashtra State, india, during kharif, 2011. The farm is located at an Altitude of 633.8 m, Latitude 18° 24 N and Longitude 76° 36 E, under moderate to assured rainfall zone (652.4 mm). where the soil was medium to black with pH 7. 0-7.9and temperature range between 11°C and 38.3°C with 15% - 91% relative humidity. Each accession was sown in one rows of 3 m length spacing of 60 cm between rows and 30 cm between plants following. Augmented Design (Federer and Ragavarao, 1975) with one replication in three blocks with three checks namely LSF-8, CS-11and Modern. At maturity five plants from each accession were selected randomly for

collect data on yield and yield related characters *viz.*, length and width of leaf lamina, petiole length, days to 50 per cent flowering, days to maturity, plant height, number of leaves plant⁻¹, head diameter, oil content, hull content, seed filling per cent, 100-seed weight and seed yield plant⁻¹. The genotypic coefficients of variation (GCV) and phenotypic coefficients of variation (PCV) were computed following Burton and Devane (1953), heritability (h²) following Hanson *et al.* (1956) and expected genetic advance over mean (GAM) as suggested by Johnson *et al.* (1955).

The accessions were characterised into on the basis of recommended qualitative characters as per DUS guidelines (Dillon *et al.* 2010) *viz.*, early plant vigour, leaf margin, leaf colour, stem and leaf pubescence, leaf shape, disc and ray floret colour, type of branching, head shape, head position and seed colour. A basal dose of 20 kg N ha⁻¹, 50 kg P₂O₅ ha⁻¹ and 40 kg K₂O ha⁻¹ was applied at the time of sowing. One month after sowing 20 kg N ha⁻¹ was given at the top dressing. All Recommended agronomic practice and prophylactic measures were adopted for raising a good and healthy.

RESULTS AND DISCUSSION

Significant variation in most of the 13 characters is evident from the mean squares (Table 1). Range, genotypic and phenotypic variance, genotypic and phenotypic coefficients of variation, heritability estimates and predicted genetic advance over mean for the respective characters are presented in Table 2. The highest GCV and PCV and their close correspondence found for seed yield plant⁻¹ (56.5% and 57.0%), and 100-seed weight (25.6% and 27.7%) indicated selection. High estimates of PCV and GCV for these characters have earliar been reported by Virupakshappa and Sindagi (1987); Gangappa (1991); Suma and Virupakshappa (1994); Reddy and Reddy (2006) and Kalukhe *et al.* (2010).

Table 1: Analysis of variance (mean squares) for seed yield and yield component

*,** significance at 5% &1% level respectively

High heritability coupled with high genetic advance as per cent of means observed for seed yield plant⁻¹ (98.1%, 115.3%) and number of leaves plant⁻¹ (93.9%, 38.2%) length and width leaf lamina, plant height, 100-seed weight, petiole length and head diameter revealed scope for their improvement through direct selection. Similar results were reported by Gangappa (1991), Jayaramaiah *et al.* (1994) and Makane *et al.* (2011). Germplasm, characterization indicated wide variation for all the qualitative characters among the accessions. Greater variation was observed early plant vigour, leaf margin, leaf

colour, stem and leaf pubescence, leaf shape, colour of disc and ray florets, type of branching, head shape, head position and seed colour. The present findings are in conformity to earlier reports of Virupakshappa and Sindagi (1987).

The accession GMU-312 recorded the highest length (32.50 cm) and width (35.00 cm) of leaf lamina and EC-552038 (30.00 cm) exhibited the highest petiole length. The accessions GMU-437, GMU-438 and GMU-443 revealed to be early flowering (50 days) but considering maturity GA-2 (83.3 days) was the earliest; similarly accessions GMU-1131 (71 days)

 $PV = Phenotypic \ variance; GV = Genotypic \ variance; h^2 = Heritability; GAM = Genetic \ advance \ over \ mean \ advance \ bar{ore} \ bar{o$

and EC-601807 (72 days) were late in flowering but GP-115 (103 days) and EC-601807 (103.17 days) took highest number of days to mature. Thus no relation between earliness or lateness in flowering and maturity could be discerned. Considering plant height GMU-476 was the tallest (196.17 cm) and EC-6019514 (105.17 cm) and GP-113 (108 cm) was dwarf. Head diameter was largest in GMU-476 (20.50 cm) and TBS-2 (21.00 cm) but was the smallest in EC-601958 (8.00 cm). Highest number of leaves could be recorded from GMU-558 (35) and DGP-21 (35) but, the least from GMU-443 (11) and GMU-327 (11). Seed filling was the highest in GMU-376 (91.40) and the least in GMU-589 (59.40 %). Considering oil per cent GMU-483 (43.85 %) produced the highest mean and ID-4005 (27.05 %) produced the lowest mean. Considering hundred seed weight GMU-308 had the highest mean of 9.00 g and revealed to be a promising accession for confectionary purpose. The lowest hull (25.20 %) could be recorded from GMU-342 but it was highest in GMU-475 (39.40 %). Maximum seed yield plant⁻¹ was observed in accession GMU-571 (124 g) followed by EC-552038 (121.50 g), which can be used for breeding for high yielding lines.

Thus, it can be concluded that no accession was found to be promising for all the quantitative characters. However, some accessions could be identified as promising for different traits with compared to the best check (Table 4). Thus, a gene pool can be generated by constituting the germplasm lines of interest or by creating a broad based cross. Such material could be useful as a base population to develop promising populations and lines.
