ABSTRACT

The traditional Back-propagation Neural Network (BPNN) Algorithm is widely used in solving many real time problems in world. But BPNN possesses a problem of slow convergence and convergence to local minima. Previously, several modifications are suggested to improve the convergence rate of Gradient Descent Back-propagation algorithm such as careful selection of initial weights and biases, learning rate, momentum, network topology, activation function and 'gain' value in the activation function. This research proposed an algorithm for improving the current working performance of Back-propagation algorithm by adaptively changing the momentum value and at the same time keeping the 'gain' parameter fixed for all nodes in the neural network. The performance of the proposed method known as 'Gradient Descent Method with Adaptive Momentum (GDAM)' is compared with the performances of 'Gradient Descent Method with Adaptive Gain (GDM-AG)' and 'Gradient Descent with Simple Momentum (GDM)'. The efficiency of the proposed method is demonstrated by simulations on five classification problems. Results show that GDAM can be used as an alternative approach for BPNN because it demonstrate better accuracy ratio on the chosen classification problems.

KEYWORDS

gradient descent, neural network, adaptive momentum, adaptive gain, back-propagation.

1 INTRODUCTION

Artificial Neural Networks (ANNs) are logical methods modeled on the learning processes of human brain. Artificial Neural Networks (ANNs) works by processing information like biological neurons in the brain and consists of small processing units known as Artificial Neurons, which can be trained to perform complex calculations. Since its advent, ANN has shown its mettle in solving many complex real world problems such as predicting future trends based on the huge historical data of an organization. ANN have been successfully implemented in all engineering fields such as biological modeling, decision and control, health and medicine, engineering and manufacturing, marketing, ocean exploration and so on [1-5].

A typical multilayer feed-forward neural network consists of an input layer, hidden layer and an output layer of neurons. Every node in a layer is connected to every other node in the

neighboring layer. Back-Propagation Neural Network (BPNN) algorithm is the most popular and the oldest supervised learning multilayer feed-forward neural network algorithm proposed by Rumelhart, Hinton and Williams [6]. The BPNN learns by calculating the errors of the output layer to find the errors in the hidden layers. Due to this ability of Back-Propagating, it is highly suitable for problems in which no relationship is found between the output and inputs. Due to its flexibility and learning capabilities it has been successfully implemented in wide range of applications [7]. Although BPNN has been used successfully it has some limitations. Since it uses gradient descent learning rule which requires careful selection of parameters such as network topology, initial weights and biases, learning rate value, activation function, and value for the gain in the activation function should be selected carefully. An improper choice of these parameters can lead to slow network convergence, network error or failure. Seeing these problems, many variations in gradient descent BPNN algorithm have been proposed by previous researchers to improve the training efficiency. Some of the variations are the use of learning rate and momentum to speed-up the network convergence and avoid getting stuck at local minima. These two parameters are frequently used in the control of weight adjustments along the steepest descent and for controlling oscillations [8].

2 BPNN WITH MOMENTUM COEFFICIENT (α)

Momentum-coefficient (α) is a modification based on the observation that convergence might be improved if the oscillation in the trajectory is smoothed out, by adding a fraction of the previous weight change [6], [9]. Thus, the addition of momentum-coefficient can help smooth-out the descent path by preventing extreme changes in the gradient due to local anomalies [10]. So it is essential to suppress any oscillations that results from the changes in the error surface [11].

In initial studies, momentum-coefficient was kept fixed but later studies on static momentum-coefficient revealed that Back-propagation with Fixed Momentum (BPFM) shows acceleration results when the current downhill of the error function and the last change in weights are in similar directions, when the current gradient is in an opposing direction to the previous update, BPFM will cause the weight direction to be updated in the upward direction instead of down the slope as desired, so in that case it is necessary that the momentum-coefficient should be adjusted adaptively instead of keeping it fixed [12], [13].

Over the past few years several adaptive-momentum modifications are proposed by researchers. One such modification is Simple Adaptive Momentum (SAM) [14], proposed to further improve the convergence capability of BPNN. Sam works by scaling the momentum-coefficient according to the similarities between the changes in the weights at the current and previous iterations. If the change in the weights is in the same ‘direction’ then the momentum-coefficient is increased to accelerate convergence to the global minima otherwise momentum-coefficient is decreased. SAM is found to lower computational overheads then the Conjugate Gradient Descent and

Conventional BPNN. In 2009, R. J. Mitchell adjusted momentum-coefficient in a different way than SAM [14], the momentum-coefficient was adjusted by considering all the weights in the Multi-layer Perceptrons (MLP). This technique was found much better than the previously proposed SAM [14] and helped improve the convergence to the global minima possible [15].
In 2007, Nazri et al. [16] found that by varying the gain value adaptively for each node can significantly improve the training time of the network. Based on Nazri et al. [16] research, this paper propose further improvement on the current working algorithm that will change the momentum value adaptively by keeping the gain value fixed.

3 THE PROPOSED ALGORITHM

There are certain reasons for the slow convergence of the Gradient Descent Back propagation algorithm. Mostly, the magnitude and direction components of the gradient vector play a part in the slow convergence. When the error surface is fairly flat along a weight dimension, the derivative of the weight is small in magnitude. Therefore many steps are required and weights are adjusted by a small value to achieve a significant reduction in error. On the other hand, if the error surface is highly curved along a weight dimension, the derivative of the weight is large in magnitude. Thus, large weight value adjustments may overshoot the minimum of the error surface along that weight dimension. Another reason for the slow rate convergence of the gradient descent method is that the direction of the negative gradient may not point directly toward the minimum error surface [17].
In-order to increase the accuracy in the convergence rate and to make weight adjustments efficient on the current working algorithm proposed by Nazri et al. [16], a new Gradient Descent Adaptive Momentum Algorithm (GDAM) is proposed in the following section.

3.1 Gradient Descent Adaptive Momentum (GDAM) Algorithm

The Gradient Descent Back propagation uses two types of training modes which are incremental mode and batch mode. In this paper, batch mode training is used for the training process in which momentum, weights and biases are updated for the complete training set which is presented to the network. The following iterative algorithm known as Gradient Descent Adaptive Momentum Algorithm (GDAM) is proposed which adaptively changes the momentum while it keeps the gain and learning rate fixed for each training node. Mean Square Error (MSE) is calculated after each epoch and compared with the target

```
For each epoch,
For each input vector,

Step-1:
      Calculate the weights
      and biases using the
      previous momentum
      value
Step-2:
      Use the weights and
      biases to calculate
      new momentum value.

End input vector
IF Gradient is increasing,
increase momentum

ELSE decrease momentum
Repeat the above steps until
the network reaches the
desired value.

End epoch
```

error. The training continues until the target error is achieved.

The gradient descent method is utilized to calculate the weights and adjustments are made to the network to minimize the output error. The output error function at the output neuron is defined as;

$$E = \frac{1}{2}\sum_{k=1}^{n}(t_k - o_k(\alpha_k))^2 \qquad (1)$$

An activation function plays a vital role in limiting the amplitude of the output neuron and generates an output value in any predefined range. Back propagation supports a lot of activation functions such as tangent, linear, hyperbolic and log-sigmoid function etc. This research will use log-sigmoid activation function which has a range of [0,1] in finding the output on the jth node;

$$O_j = \frac{1}{1 + e^{-a_{net,j}}} \qquad (2)$$

where,

$$a_{net,j} = \left[\sum_{i=1}^{I} w_{ij} O_i\right] + \theta j \qquad (3)$$

where,

n : number of output nodes in the output layer.

t_k : desired output of the kth output unit.

O_k : network output of the kth output unit.

O_j : Output of the jth unit.

O_i : Output of the ith unit.

W_{ij} : weight of the link from unit i to unit j.

$a_{net,j}$: net input activation function for the jth unit.

θ_j : bias for the jth unit.

$\frac{\partial E}{\partial \alpha_k}$, needs to be calculated for the output units and $\frac{\partial E}{\partial \alpha_j}$ is also required to be calculated for hidden units, so that the respective momentum value can be updated in the Equation (6):

$$\Delta \alpha_k = \left(-\frac{\partial E}{\partial \alpha_k}\right) \qquad (4)$$

$$\Delta \alpha_j = \left(-\frac{\partial E}{\partial \alpha_j}\right) \qquad (5)$$

$$\frac{\partial E}{\partial \alpha_k} = (t_k - O_k)O_k(1 - O_k)(\sum w_{jk} O_j + \theta_k) \qquad (6)$$

The momentum update expression from input to output nodes becomes;

$$\Delta\alpha_k(n+1) = (t_k - O_k)O_k(1 - O_k)(\sum w_{jk} O_j + \theta_k) \qquad (7)$$

$$\frac{\partial E}{\partial \alpha_j} = \left[-\sum_k \alpha_k w_{jk}(t_k - O_k)O_k(1 - O_k)\right] O_j(1 - O_j)\left[\left[\sum_j w_{ij} O_i\right] + \theta_j\right] \qquad (8)$$

Therefore, the momentum update expression for the hidden units is:

$$\Delta\alpha_j(n+1) = \left[-\sum_k \alpha_k w_{jk}(t_k - O_k)O_k(1 - O_k)\right] O_j(1 - O_j)\left[\left[\sum_j w_{ij} O_i\right] + \theta_j\right] \qquad (9)$$

Weights and biases are calculated in the same way, the weight update expression

for the links connecting to the output nodes with a bias is;

$$\Delta w_{jk} = (t_{k\_} O_k) O_k (1 - O_k) \alpha_k O_j \qquad (10)$$

Similarly, bias update expression for the output nodes will be;

$$\Delta \theta_k = (t_{k\_} O_k) O_k (1 - O_k) \alpha_k \qquad (11)$$

The weight update expression for the input node links would be:

$$\Delta w_{ij} = \left[\sum_k \alpha_k w_{jk} (t_{k\_} O_k) O_k (1 - O_k) \right] \alpha_j O_j (1 - O_j) O_i \qquad (12)$$

And, finally the bias update expression for hidden nodes will be like this;

$$\Delta \theta_j = \left[\sum_k \alpha_k w_{jk} (t_{k\_} O_k) O_k (1 - O_k) \right] \alpha_j O_j (1 - O_j) \qquad (13)$$

4 RESULTS AND DISCUSSIONS

Basically, the main focus of this research is to improve the Accuracy of the network convergence. Before discussing the simulation test results there are certain things that need be explained such as tools and technologies, network topologies, testing methodology and the classification problems used for the entire experimentation. The discussion is as follows:

4.1 Preliminary Study

The Workstation used for carrying out experimentation comes equipped with a 2.33GHz Core-2 Duo processor, 1-GB of RAM while the operating system used is Microsoft XP (Service Pack 3). The improved version of the proposed algorithms by Nazri [17] is used to carry-out simulations on MATLAB 7.10.0 software. For performing simulations, three classification problems like Breast Cancer (Wisconsin) [18], IRIS [19], and Australian Credit Card Approval [20] are selected. The following three algorithms are analyzed and simulated on the problems:

1) Gradient Descent with Simple Momentum (GDM),
2) Gradient Descent Method with Adaptive Gain (GDM-AG), [16] and
3) Gradient Descent with Adaptive Momentum(GDAM)

Three layer back-propagation neural networks is used for testing of the models, the hidden layer is kept fixed to 5-nodes while output and input layers nodes vary according to the data set given. Global Learning rate of 0.4 is selected for the entire tests and gain is kept fixed. While log-sigmoid activation function is used as the transfer function from input layer to hidden layer and from hidden layer to the output layer. In this research, the momentum term is varied adaptively between the range of [0,1] randomly . For each problem, trial is limited to 3000 epochs. A total of 15 trials are run for each momentum value. The network results are stored in the result file for each trial. Mean, standard deviation (SD) and the number of failures are recorded for each independent trial on Breast Cancer (Wisconsin) [18], IRIS [19], and Australian Credit Card Approval [20], Pima Indian Diabetes Problem[21], and Heart Disease[22].

4.2 Breast Cancer (Wisconsin) Classification Problem

Breast Cancer Dataset was taken from UCI Machine Learning Repository databases. The dataset was created on the information gathered by Dr. William H. Wolberg [18] during the Microscopic study of breast tissue samples selected for the diagnosis of breast cancer. This problem deals with the classification of breast cancer as benign or malignant. The selected feed forward neural network architecture used for this classification problem is 9-5-2. The target error is set to 0.01. The best momentum values for GDM and GDM-AG is 0.6 and 0.7 respectively. While for GDAM, the best momentum value is found in the interval $[0.3-0.8]$.

Table-1. Algorithm Performance for Breast Cancer Problem [18]

Breast Cancer Problem, Target Error = 0.01			
	GDM	GDM-AG	GDAM
Accuracy (%)	92.8	94.0	94.71
SD	10.7	6.98	0.19
Failures	0	0	0

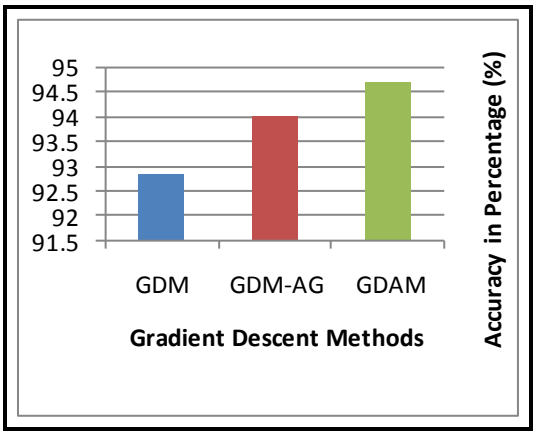

Figure-1. Performance comparison of GDM, GDM-AG and GDAM for Breast Cancer Classification Problem

Table-1, shows that the proposed algorithm (GDAM) shows far better performance in reaching the desired target error value of 0.01 than the previous improvements used for comparison. The proposed algorithm (GDAM) gives 94.71 percent accuracy when the network converges while GDM and GDM-AG is a left behind with 92.84 and 94.0 percentile accuracies respectively. Figure-1 clearly shows that GDAM outperforms GDM with an accuracy improvement ratio of 1.02.

4.3 IRIS Classification Problem

IRIS flower data set classification problem is one of the novel multivariate dataset created by Sir Ronald Aylmer Fisher [19] in 1936. IRIS dataset consists of 150 instances from Iris setosa, Iris virginica and Iris versicolor. Length and width of sepal and petals is measured from each sample of three selected species of Iris flower. The feed forward network is set to 4-5-2. The target error is set to 0.01. For Iris, the

best momentum value for GDM and GDM-AG is 0.2. While for GDAM, the best momentum value is found in the interval $[0.6-0.8]$.

Table-2. Algorithm Performance for IRIS problem [19]

IRIS Problem, Target Error = 0.01			
	GDM	GDM-AG	GDAM
Accuracy (%)	93.85	90.63	94.09
SD	0.23	3.46	1.09
Failures	1	3	0

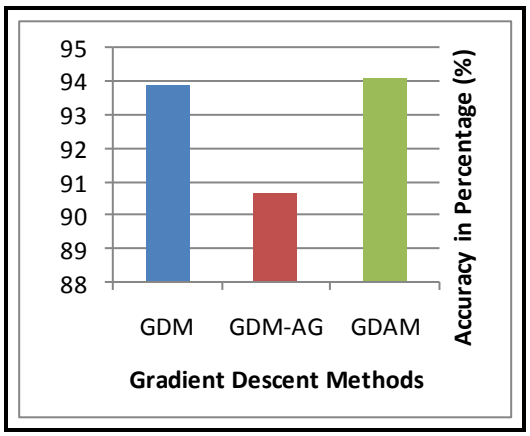

Figure-2. Performance comparison of GDM, GDM-AG and GDAM for IRIS Classification Problem

From the Table-2, it is easily seen that the proposed algorithm (GDAM) is superior in performing convergence with a percentile accuracy of 94.09 which is better than the accuracies shown by GDM and GDM-AG. Also, it can be noted that GDM and GDM-AG have a failure rate of 1 and 3 respectively. In the Figure-2, GDAM can be seen outperforming GDM with an accuracy ratio of 1.0.

4.4 Australian Credit Card Approval Classification Problem

Australian Credit Approval dataset is taken from the UCI Machine learning repository. With a mix of 690 instances, 51 inputs and 2 outputs, this dataset contains all the details about credit card applications. Each instance in this data set represents a real credit card application and the output describes whether the bank (or similar institution) will grant the credit card or not. It was first submitted by Quinlan in 1987 [20]. All attribute names and values have been changed to meaningless symbols to protect confidentiality of the data. The feed forward network architecture for this classification problem is set to 51-5-2. The target error is again set to 0.01. For Australian Credit Card Approval, GDM and GDM-AG both have the same best momentum value of 0.4. GDAM works best on the momentum value interval of $[0.7-0.8]$.

Table-3. Algorithm Performance for Australian Credit Card Approval [20]

Australian Credit Card Problem, Target Error = 0.01			
	GDM	GDM-AG	GDAM
Accuracy (%)	94.28	91.05	96.60
SD	1.15	11.87	0.53
Failures	1	1	0

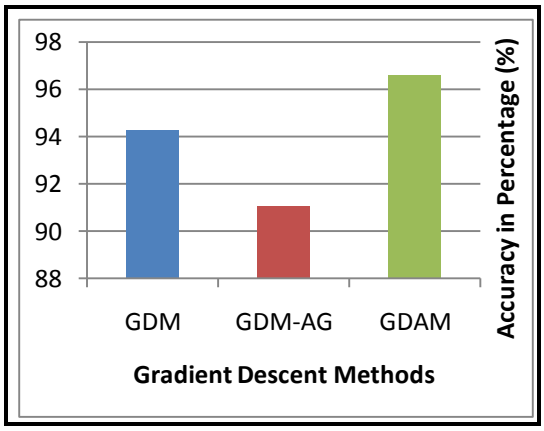

Figure-3. Performance comparison of GDM, GDM-AG and GDAM for Australian Credit Card Approval Classification Problem

It is apparent from the Table-3, that GDAM is giving a percentile accuracy of 96.60 during convergence. Here also GDM and GDM-AG show 1 failed trial while there is no failure with GDAM even once on this classification problem. From the Figure-3, GDAM clearly shows an accuracy ratio of 1.02 on GDM.

4.5 Pima Indians Diabetes Problem

Pima Indians Diabetes dataset is taken from the UCI Machine learning repository. Consisting of 768 instances, 8 inputs and 2 outputs, this dataset contains all the information of the chemical changes in a female body whose imbalance can cause diabetes. The feed forward network architecture for this classification problem is set to 8-5-2. The target error is again set to 0.01. For Pima Indians Diabetes, GDM and GDM-AG have the best momentum values of 0.3 and 0.2 respectively. GDAM works best on the momentum value interval of $[0.6-0.8]$.

Table-4. Algorithm Performance for Pima Indians Diabetes Problem [21]

Pima Indians Diabetes Problem, Target Error = 0.01			
	GDM	GDM-AG	GDAM
Accuracy (%)	70.81	67.81	75.73
SD	2.07	3.63	0.54
Failures	2	5	0

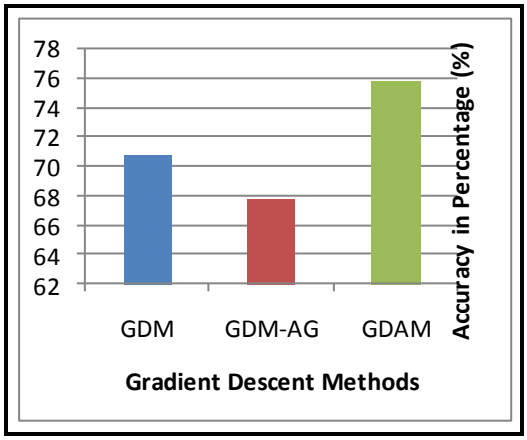

Figure-4. Performance comparison of GDM, GDM-AG and GDAM for Pima Indian Diabetes Classification Problem

As seen from the Table-4, that GDAM is showing a percentile accuracy of 75.73 during convergence. Here GDM show 2 and GDM-AG show 5 failed trials while GDAM stays stable throughout. From the Figure-4, GDAM clearly shows an accuracy ratio of 1.06 on GDM.

4.6 Heart Disease Problem

Collected from UCI Machine learning repository, Heart Disease dataset consist of 303 instances, 13 inputs and 1 output. This dataset deals with all the symptoms of a heart disease present in a patient on the basis of information given as input.

The feed forward network architecture for this classification problem is set to 13-5-1. Again, the target error is set to 0.01. For Heart Disease, GDM and GDM-AG have the best momentum values of 0.4 and 0.7 respectively. GDAM works best on the momentum value interval of $[0.3-0.8]$.

Table-5. Algorithm Performance for Heart Disease Problem [22]

Heart Disease Problem, Target Error = 0.01			
	GDM	GDM-AG	GDAM
Accuracy (%)	88.77	83.97	91.76
SD	9.71	3.63	3.57
Failures	2	3	0

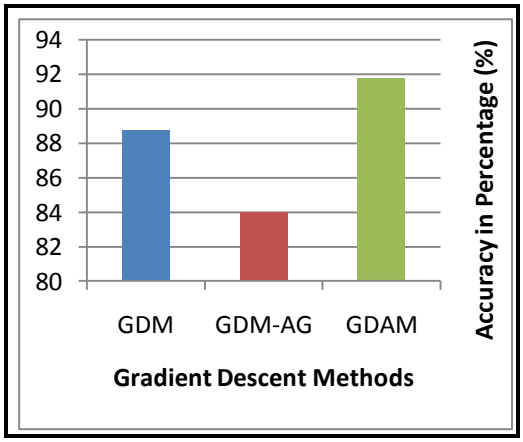

Figure-5. Performance comparison of GDM, GDM-AG and GDAM for Heart Disease Classification Problem

Table-5, shows that GDAM is showing a high percentile accuracy of 91.76 which is much higher if compared with old methods. Here GDM and GDM-AG are showing failures while GDAM is again showing stability during convergence. In Figure-5, the comparison of accuracies between GDAM, GDM and GDM-AG on heart disease dataset can be seen.

5 CONCLUSIONS

The Back-propagation Neural Network (BPNN) is a supervised learning neural network model highly applied in different engineering fields around the globe. However, it has a problem of slow convergence and network collapse which still needs to be answered. This paper proposed a further improvement on the current working algorithm by Nazri[17]. The 'Gradient Descent Method with Adaptive Momentum (GDAM)' works by adaptively changing the momentum and keeping the 'gain' parameter fixed for all nodes in the neural network. The performance of the proposed GDAM is compared with 'Gradient Descent Method with Adaptive Gain (GDM-AG)' and 'Gradient Descent with Simple Momentum (GDM)'. The performance of GDAM is verified by means of simulation on the five classification problems. The final results show that GDAM has performed well for all classification problems than the previous methods.
