### Abstract

Autophagy is a catabolic mechanism developed in eukaryotes in order to maintain cellular homeostasis and development. It is also an essential constituent of the immune system since it is involved in the MHC class I and II antigen generation and exerts an antiviral effect. However many viruses are either able to inhibit or induce autophagy to avoid their own elimination or to favor their replication by interacting with different complexes of the autophagy pathway. This review summarizes the molecular mechanisms of autophagy and its importance in immunity. It describes the different strategies that viruses have adopted to hijack this process.

**Keywords:** Autophagy; Antigen processing and presentation; MHC Class I and II; CD4<sup>+</sup> T cells; Viral infection; Immune evasion

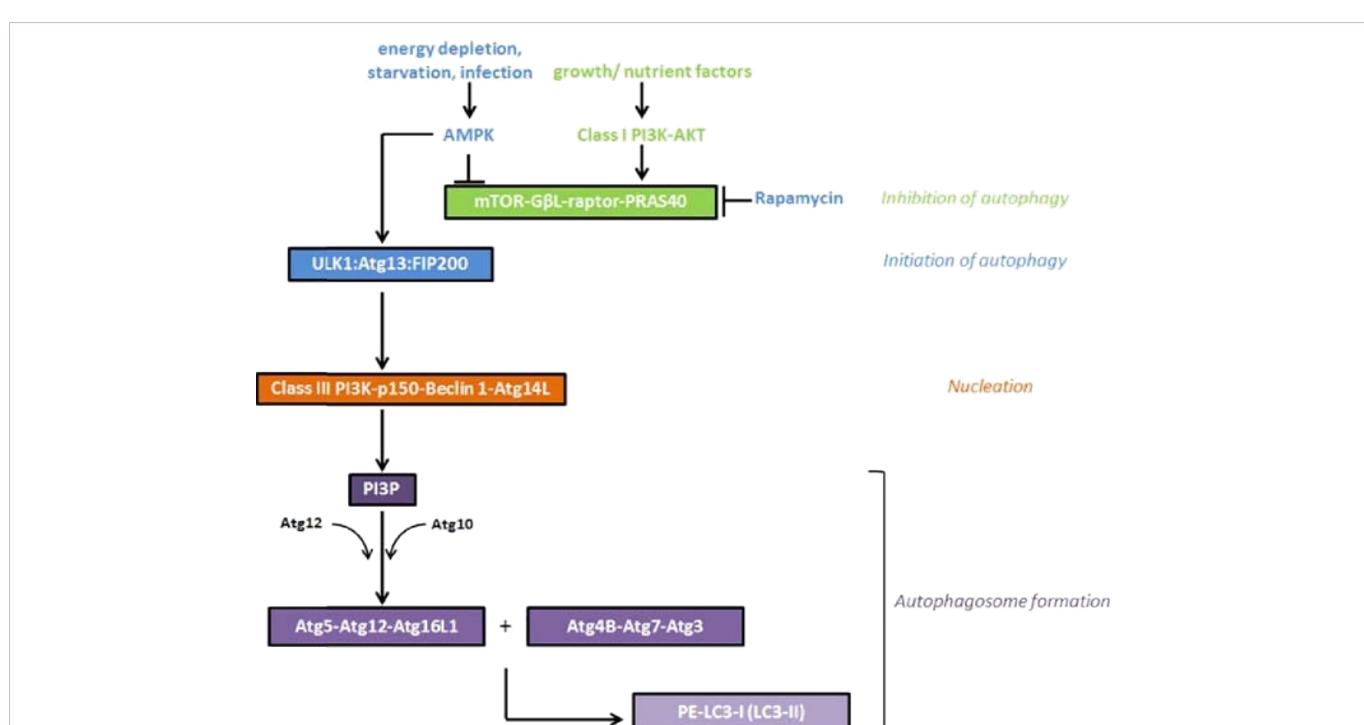

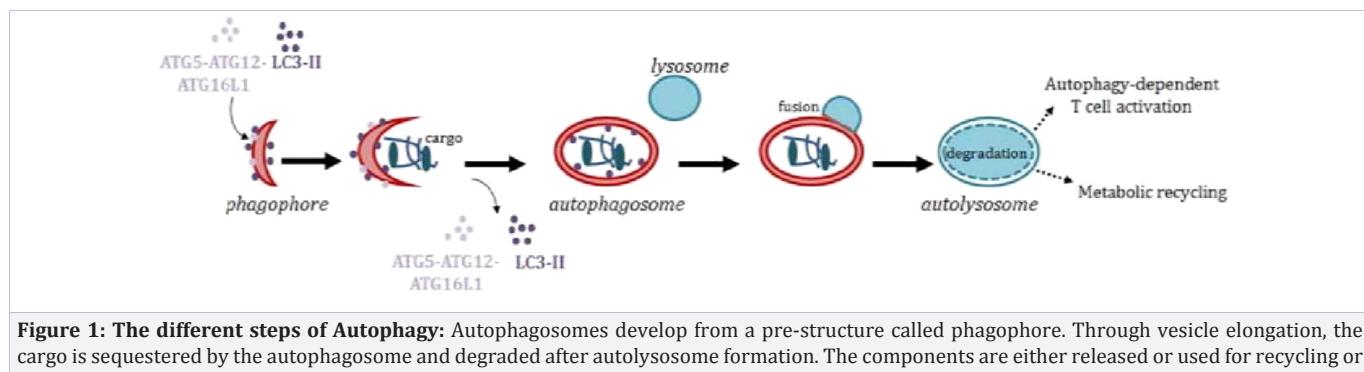

### Introduction

Extracellular antigens are taken up through endocytosis. Activation of specific proteases leads to acidification of endosomal vesicles and degradation of exogenous proteins into peptides. Contrary to micro- or chaperone mediated autophagy, where the substrates are directly delivered to lysosomes for degradation, macroautophagy (hereafter referred to as autophagy) is divided into different phases starting with the formation of autophagosomes, generated from a pre-autophagosomal structure known as phagophore. Autophagosomes were detected in the late 1950's for the first time in mammalian cells through electron microscopy [1,2]. They belong to double-membrane vesicles that are responsible for the sequestration of cytosolic components, including damaged organelles, polyubiquitinated protein aggregates and pathogens [3]. Their fusion with lysosomes contributes to the formation of autolysosomes, which promote cargo degradation and vesicle break-down conducted by acidic hydrolases (Figure 1). Autophagy is also defined as a process which occurs in eukaryotic cells, and can either be induced or inhibited to maintain tissue homeostasis and development. However, since defective autophagy is associated with numerous diseases such as chronic inflammatory diseases (e.g. neurodegenerative or pulmonary diseases) or cancer, it plays an essential role in immunity [4]. For this reason, pathogens and especially viruses have developed specific mechanisms to inhibit autophagy or to take advantage from this machinery for their own replication and by this way to manipulate or evade the immune system.

### Molecular Regulation of Autophagy

Autophagy was originally identified by Ashford and Porter in rat hepatocytes and described to be a cellular response to starvation [5]. Autophagy-related genes (Atgs), which were actually identified in yeast, are conserved in eukaryotic cells and participate in autophagosome formation [6-8]. Energy depletion, starvation or infection, are responsible for activation of autophagy, which involves the induction of a highly sophisticated signaling cascade initiated by the AMP- Activated Protein Kinase (AMPK)-mediated stimulation of the ULK1:Atg13:FIP200 complex as described below [4]. In the presence of growth or nutrient factors like insulin or amino acids, mammalian Target of Rapamycin (mTOR) is stimulated and autophagosome formation is disabled [Figure2] [9]. mTOR is a 280 kDa large Ser/Thr protein kinase, which is implicated into cellular metabolism regulation [10]. mTOR resides in two complexes mTORC1 and mTORC2 [11]. mTORC2 is rapamycin insensitive and mainly responsible for the rearrangement of actin cytoskeleton [12]. On the other hand, mTORC1 is rapamycin sensitive and constituted of mTOR, The G protein beta subunit-like protein (G $\beta$ L), the regulatory associated protein of mTOR (raptor) and the Proline-Rich Akt/PKB substrate 40 kDa (PRAS40). It monitors protein synthesis, nutrient import and Autophagy [10,11,13,14]. mTORC1 activation is controlled by the class I Phosphatidylinositol 3-Kinase (PI3K)-AKT pathway through perception of growth factors [13,15]. In the case of energy deprivation and ATP decrease, mTORC1 blockage is mediated via AMPK to stimulate autophagy [15]. Autophagy is triggered by stimulating the ULK1:Atg13:FIP200 complex through inhibition of mTOR [16-18]. The Unc- 51-like Kinase (ULK)-1 and the 200 kDa focal adhesion kinase family- interacting protein (FIP200) interact with Atg13, which in turn is stabilized by the expression of Atg101 [11,19,20]. Phagophore nucleation and assembly necessitate the initiation of the PI3K complex, composed of the class III PI3K, the regulatory protein kinase p150, Beclin 1 and Atg14L, a Beclin 1-associated key regulator [21,22]. This results in the production of Phosphatidylinositol-3-Phosphate (PI3P), which enables autophagosome formation (Figure 2).

Vesicle elongation is promoted by two ubiquitin-like conjugation systems [9]. For the first system, Atg12 is activated

by the E1-like enzyme Atg7 and conjugation of Atg12 to Atg5 is sustained by the E2-like enzyme Atg10. Binding of Atg16L1 to Atg5-Atg12, which exhibits an E3-like enzyme activity, contributes to the generation of a heterotrimeric complex, located at the phagophore membrane. This complex, together with the Atg4B protease, Atg7 and Atg3, encompass the second ubiquitin-like conjugation system, which establishes the interaction between phosphatidyl Ethanolamine (PE) and the microtubule-associated protein light chain 3 (LC3-I, mammalian homolog of Atg8). The conversion of LC3-I to the lipidated and membrane-associated form LC3-II (PE conjugated) is a common marker and regulator for autophagosome formation that directs further steps of Autophagy [9].

After fusion of lysosome with autophagosome, specific acidic hydrolases are released inside of the autolysosome, leading to

cargo degradation and finally to vesicle breakdown for metabolic recycling (Figure 1). Previous investigations demonstrated that autophagy is strongly implicated into the adaptive immune response especially in the generation of Major Histocompatibility Complex (MHC) class II restricted antigens [23-25] but can also be involved in innate immunity and generation of MHC class I peptides as described below.

### Autophagy-Related MHC class I and II Peptide Generation

Infectious, pathogen-derived antigens are presented by MHC class I or II molecules to surveilling T-cells. Contrary to MHC class I molecules, which are expressed on all nucleated cells, MHC class II is only found on professional Antigen Presenting Cells (APCs) like Dendritic Cells (DCs), B-cells, macrophages and certain epithelial cells. Additionally, MHC class I antigens are from cytosolic origin

and processed by proteasomes to be translocated into the endoplasmic reticulum (ER) via the Transporter Associated with antigen Processing (TAP) [26]. However MHC class I peptides can also be generated through Autophagy. This was firstly shown by English et al. in the context of HSV-1 infected macrophages [27], which identified the implication of a vacuolar pathway in the generation of endogenous MHC class I antigens for CD8<sup>+</sup> T-cell stimulation. Although this process differs in some aspects from the conventional macroautophagy, e.g. detection of two and four layered membrane structures, accumulation of LC3 molecules and the dependence on Atg5 at 6-8 hours post infection revealed the existence of a connection between autophagy and MHC class I antigen presentation [27]. An alternative autophagy-mediated endogenous MHC class I peptide presentation was characterized as being TAP-independent and implied the use of a vacuolar pathway. This was described for the Human Cytomegalovirus (HCMV) - encoded pUL138 protein, which can either be generated by the conventional route or through lysosomal proteases [28]. MHC class I molecules are also known to present extracellular antigens in APCs to CD8<sup>+</sup> T-cells via cross-presentation [29]. In line with this, knockdown of specific Atgs (e.g. Beclin-1 and Atg12) in tumor cells caused a significant decrease in cross-presentation. This assumes the dependence of cross-presentation on autophagy, playing an essential role in antigen delivery to DCs, although the exact mechanism is not completely understood [30].

Regarding MHC class II antigens, they are mainly generated from exogenous proteins [31,32] but can also be from nuclear and cytosolic origin if processed through Autophagy [31,33]. In support of this notion, 20- 30% of natural MHC class II ligands turned out to be derived from endogenous proteins produced through Autophagy [2,23,34]. To provide efficient antigen presentation, the MHC class II  $\alpha$ - and  $\beta$ -chain assemble in the ER and interfere with the invariant chain (Ii), to prevent the binding of premature epitopes. Thus, this complex is transported to the acidic endosomal MHC class II compartment (MIIC) within APCs, where Ii is digested, leaving a class II associated Ii peptide (CLIP). The binding of MHC class II antigens is mediated by HLA-DR, being responsible for the dissociation of CLIP from the peptide binding groove. Antigens generated via autophagy are delivered to MHC class II molecules through direct fusion of autophagosomes with MIIC, or with endosomes which then in turn merge with MIIC [35,36]. A recent study posits the existence of endosome-mediated autophagy in DCs, characterized by the formation of MIIC-derived autophagosomes [37], which supplementary confirms the relationship between autophagy and MHC class II antigen presentation. Hence, the MHC class II complex is released from MIIC and peptides are presented to CD4<sup>+</sup> T- cells [Figure 3] [31].

## Autophagy in Innate and Adaptive Immunity

In case of an infection, it's well known that APC activation is conducted through binding of pathogens to Pattern-Recognition Receptors (PRRs) which are subdivided into different classes, comprising the membrane-bound Toll-like Receptors (TLRs). TLRs recognize microbial patterns to induce an innate immune response which is initially implemented by a downstream

signaling cascade, including the adaptor molecules myeloid differentiation primary-response protein 88 (MyD88) and TIR domain-containing adaptor protein inducing interferon  $\beta$  (TRIF), with ensuing release of type I interferons and pro-inflammatory cytokines from innate immune cells like dendritic cells or macrophages [38]. MyD88 and TRIF were described to be involved in activation of autophagy by targeting Beclin-1 [39], emphasizing a direct connection between pathogen recognition and autophagy induction. Here, autophagy serves as an initial response but is additionally known to be a key component of the adaptive immune system.

The importance of Autophagy was also defined in the context of lymphocyte development and activity. The up-regulation of co-stimulatory signals released by APCs, sustains their migration to lymphoid organs. There, APCs and naive CD4<sup>+</sup> T-cells encounter and interact with each other via detection of pathogen-peptides presented by MHC class II molecules [40], a process which is known as T-cell priming [41]. Lee and coworkers highlighted the significance of Atg5 for antigen presentation by DCs, since deletion of Atg5 affected CD4<sup>+</sup>-T cell priming upon viral infection [42]. After identification of their cognate peptide, naive CD4<sup>+</sup>-T cells undergo cell division and differentiation into T helper 1 (TH1), T helper 2 (TH2), follicular T helpers, pro-inflammatory T helper 17 or regulatory T cells, depending on the milieu of cytokines [40]. All together these cells promote the growth and survival of T-lymphocytes, macrophages, B-cells and initiate inflammatory responses in order to induce a pathogen-specific answer by the immune system. The generation of Atg5-deficient mice resulted in a decrease of T- and B-lymphocyte production and impaired their proliferation [43,44]. Li et al. detected a stronger expression of LC3-GFP dots in TH2 cells, and assumed that autophagy takes place in TH2 more than in TH1 cells [45]. Being an important component of the autophagy cascade, mice lacking class III PI3K in a specific T-cell lineage exhibited not only major defects in the autophagic flux, but moreover showed disturbed T-cell regulation and developed later on an inflammatory wasting syndrome [46]. Importance of autophagy was furthermore revealed in the context of memory B-cells in mice showing increased levels of Atgs and autophagosome formation in first instance as a response against influenza virus infection [47]. Taken together, these findings support the conclusion that autophagy is strongly involved in the control of CD4<sup>+</sup> T-cell homeostasis and is a constitutive part of the adaptive immune system.

## Anti- and proviral effects of Autophagy

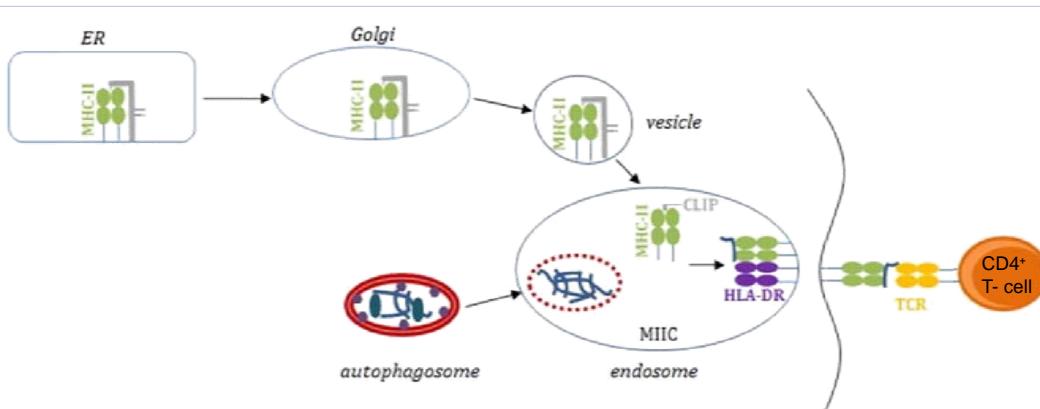

Autophagy comprises the elimination of intracellular pathogens in infected cells through lysosomal degradation. This process is commonly referred to as xenophagy [4,48]. Beside their regulatory role in autophagy, Atg proteins have been reported to be essential to mount an effective immune response to fight against viral infections [49]. The contribution of Atg proteins to cellular host defense was firstly depicted in the context of Sindbis virus infection and its regulation by Beclin 1 (also known as Atg6). Overexpression of the Bcl-2 interacting protein Beclin 1 led to an

increased survival of Sindbis virus infected mice and protection against lethal encephalitis [50]. Reed et al, [51] illustrated the constitutive role of Beclin 1 in DCs upon respiratory syncytial virus infection. Mice with severe deficiencies in autophagy emanating from Beclin 1 haploinsufficiency, exhibited a reduced MHC class II expression and down-regulation of innate cytokine synthesis, resulting in serious lung pathology as a consequence. Further studies indicated a critical role of the Atg5-Atg12/Atg16L1 complex for interferon- $\gamma$  mediated antiviral responses in norovirus-infected mice [52]. Moreover DCs, B- and epithelial cells expressing the Influenza A Matrix Protein 1 (M1) in fusion with LC3, demonstrated a 20-fold higher M1-specific MHC class II presentation to CD4 $^{+}$  T-cell clones than cells expressing M1 alone [35]. These outcomes emphasize the implication of autophagy in the host antiviral defense.

However, many viruses evolved different mechanisms to inhibit autophagy and therefore to ensure their survival and development in their host cells [Figure 4]. A very well-exploited example is the expression of Herpes Simplex Virus-1 (HSV-1) encoded inhibitory protein ICP34.5 which blocks the phosphorylation of the translation initiation factor 2 $\alpha$  (eIF2 $\alpha$ ) by interacting with Beclin-1 and Protein-Kinase R (PKR) [53]. A further HSV-1 protein called US11 was also characterized to prevent autophagy through repression of PKR [54]. Further investigations represented the inhibitory role of the HCMV protein TRS1 on autophagy during the late phase of infection [55]. This effect could either be ascribed to the interaction of TRS1 with PKR [56] or as demonstrated by Chaumorcel et al. to binding of TRS1 to Beclin 1 [55]. First *in vitro* experiments reported interleukin-10 to be able to inhibit HCMV replication by blocking autophagy [57]. This study reinforces the existing dependence of HCMV on autophagy. In another case, infection of human lung epithelial cells with Influenza A virus (IAV) resulted in the accumulation of autophagosomes as a consequence of ceased fusion with lysosomes which could be attributed to viral Matrix Protein 2 (M2) [58]. Recent studies could show that

this is due to interaction of LC3 protein with M2, which mimics the interaction of LC3 with its interaction motif, resulting in relocalization of LC3 at the plasma membrane. This was observed at time of virus budding of IAV infected cells and was assessed to be a critical step for viral replication [59]. Additionally, Human Immunodeficiency Virus (HIV) was described to block autophagosome formation through liberation of HIV tat and interleukin-10 [3,60]. HIV nef was proved to be at the origin of restrained autophagosome maturation [3,61]. In some cases, as for Hepatitis B virus (HBV), the impact of infection on autophagy stays elusive. First publications elucidated autophagy inducing activity of HBV protein X (HBx) through stimulation of a death-associated protein kinase [62]. Although autophagosome formation and LC3 protein detection would favor the idea of HBV-induced autophagy, Liu and coworkers described HBx to impair lysosomal acidification and therefore to inhibit the autophagic degradation, having development of hepatocellular carcinoma as a consequence [63].

Disregarding prevention and repression of autophagy, viruses are even more able to induce and subvert autophagy for their own benefit [Figure 4]. Investigating this aspect, it was reported that Polio Virus (PV) infection enhances the formation of double-membrane structures [64,65] corresponding to LC3-positive vesicles [66]. These arranged membranes were suggested to originate from autophagy, for support of viral replication and release of virions [67]. Similar observations were made for another single stranded RNA virus, the Hepatitis C virus (HCV) [68,69]. Contrary to PV, autophagy is only required in the early stage of infection for translation and *de novo* synthesis of the HCV genome [70,71]. Viruses can supplementary use the autophagy machinery for their replication. Wen et al. indicated that a Kaposi's Sarcoma-associated Herpes virus (KSHV) infection causes an increase in the number of autophagic vesicles and LC3-lipidation, resulting in a reactivation and lytic replication of the virus, which was strongly down-regulated with autophagy inhibition [72]. Epstein-Barr virus (EBV) uses a similar mechanism, where

**Figure 3: MHC class II presentation of autophagy processed antigens:** MHC class II molecules and LAs assemble in the ER. The complex is then conducted from the Golgi to the MIIC through vesicle transport, where Li is digested leaving CLIP. Simultaneously, auto phagosomes fuse with endosomes or MIIC for delivery and binding of antigens to MHC class II molecules, after HLA-DR mediated their dissociation from CLIP. Thus newly peptide-loaded MHC class II complexes are transported to the cell surface and expose autophagy processed peptide epitopes to CD4 $^{+}$ -T cells to be recognized by their specific T cell receptors.

virus propagation is also provided through autophagy vesicle transport [73]. On the other hand, during the latent phase of KSHV infection, autophagy is blocked in DCs which is presumably related to phosphorylation of Signal Transducer and Activator of Transcription 3 (STAT3), causing DC dysfunction and therefore immune evasion and virus persistence in the host [74]. The supportive role of autophagy was furthermore delineated in correlation with Dengue virus (DV) infection. An increased LC3-II expression, autophagosome formation and triggered autophagic flux in brain tissues of infected suckling mice led back to enhanced autophagy, probably to promote viral replication and pathogenesis [75]. The influence and dependence of pathogens on autophagy was additionally depicted in the context of Measles virus (MeV) infection [76]. MeV infection induces autophagy via different signaling pathways to limit the number of dying cells and improve formation of viral particles. Richetta, et al. demonstrated that infection of HeLa cells with an attenuated form of MeV elicits distinct waves of autophagy, involving in a first step the MeV cellular receptor CD46 and scaffold protein Gopc. After infection, viral replication and the expression of the non-structural measles virus protein C, initiate the second wave of autophagy, which can be sustained through a third autophagy signal in infected cells, being the outcome of cell-cell fusion and formation of syncytia [76]. Viruses like Vaccinia Virus (VACV), seem to replicate independently of autophagy, but can still disrupt Autophagy [77,78]. Moloughney, et al. noticed a considerable LC3-lipidation after VACV infection, which was probably mediated through direct conjugation of Atg3 to Atg12. Despite these findings, neither autophagosome formation nor autophagic flux could be detected [77]. Nevertheless, previous investigations reported the capacity of VACV to replicate in autophagy-deficient cells as efficiently as in wild-type cells [79], indicating that virus may

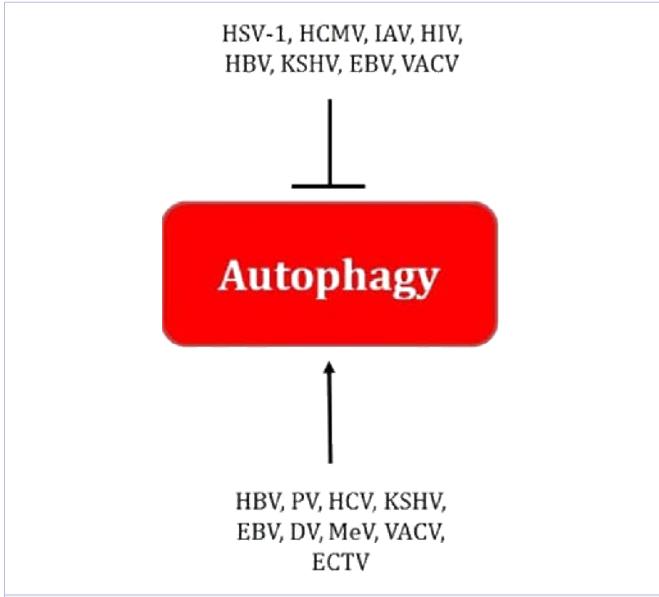

not need autophagy for replication. Ectromelia virus (ECTV), which also belongs to the poxvirus family and is known to causes disease in mice, induces autophagy too [80], however studies regarding replication of ECTV and autophagy were not directed so far. Overall there are different strategies how viruses interact with the autophagy pathway.

## Conclusion

In the last decades, autophagy has sparked huge interest and was shown to be involved in immunity. On one hand, autophagy participates in the cellular host defense through degradation of pathogens; but, on the other hand, impaired autophagy may result in neurological or immunological disorders and cancer. Additionally, during co-evolution with their mammalian host, many viruses have developed specific strategies to inhibit, manipulate or counteract the autophagy process. Acquiring deeper knowledge about the autophagy pathway, would grant further interest in how this machinery works by benefiting either the immune system or virus proliferation. These findings might be the basis for development of new viral therapeutics [81].
