Keywords: Age Infertility Semen Sperm Volume

## **1. Introduction**

During the last few decades there has been uprising debate regarding the issue of declining semen parameters which are generally considered to be a proxy measure of male fertility. Changes in semen quality can occur after occupational and environmental exposure to toxic agents[1] or from the predictor factors of the host, such as age[2]. The weight of evidences primarily from the clinical studies suggest that age is associated with diminished semen volume[3]. Also, men at older ages (e.g. 50 years) were underrepresented in many clinical studies, which restricted statistical strength and prevented unveiling of the exact form of relationship between age and semen volume. In addition, potential confounders that might explain changes with age, such as smoking history or duration of abstinence, were hardly ever taken under consideration[4]. The deterioration of semen qualities was first reported in 1974 by Nelson and Bunge[5]. In 1992, Carlsen et al.[6] reported a global decline in semen qualities between 1938 and 1990. Swan et al.[7] published a reanalysis of the studies included by Carlsen et al. [6] In that investigation, they have found significant declines in semen quality in the United States, Europe, and Australia, but no such

Tel:+91-33-22418887

in semen volume, i.e. there has been a genuine diminution in semen volume over the past 33 years. As male fertility is to some extent correlated with semen volume the results may reflect an overall reduction in male decline in non-Western countries. The similar declines were also proclaimed by numerous other studies[7,8]. A thorough dive into diverse studies from specific cites reveals evidences of declines in semen volume but a worldwide decline has not been demonstrated.

Since several decades numerous experimental and epidemiological experiments tend to establish that in

humans the semen volume declines with progression of age. This literature review is intended to report the

association between male age and semen volume. Review of English language-published research over the

last 33 years, from January 1, 1980, up to December 31, 2013, has been conveniently constructed using

MEDLINE database. Studies with inadequate numbers of subjects and case reports were excluded. Among the methodologically stronger studies, declines in semen volume of 3% - 22% were likely when comparing

30-year-old men to 50-year-old men. The report suggests that increased male age is associated with a decline

semen volume in human with increase in age by picking the scattered reports of last 33 years.

It is definitely arduous to execute a systematic, scientific study

regarding the decline in human semen quality. Thus, this review has

been intended to build-up a substantial idea regarding alterations in

#### 2. Methods of literature review

Research articles on humans published in English from January 1, 1980, through December 31, 2013 have been included in this report. The data for this review were obtained from extensive search using Medical Subject Headings (MeSH) of electronic databases which included Medline, Elsevier, Medscape, and PubMed. Relevant literature on the effect of age on the semen volume and its impact on future natural and assisted conception cycles were retrieved. Data of the subjects with normal semen analysis or clinical problems have been excluded. Studies with insufficient numbers of subjects (n <20), case reports, case series, and anecdotal data were excluded. In each case sperm volume and its outcome were evaluated. Analytic epidemiological studies were emphasized. In results section the

<sup>\*</sup>Corresponding author: Pallav sengupta, Department of Physiology, Vidyasagar College for Women, University of Calcutta, 39, Sankar Ghosh Lane, Kolkata 700 006, West Bengal, India.

relative changes in the outcome with age were represented. For example, if semen volume decreased from 4.2 mL in the younger age group to 3.6 mL in the older age group, then the relative decrease was 0.6/4.2, a 14% decrease in volume with increased age. Whenever possible, the differences between younger men (i.e., ages 30 years) and older men (i.e., ages 50 years) were summarized.

## 3. Discussion: scenario of last 33 years

During the retrieval of relevant documents, it has been found a total of forty eight studies have evaluated the relationship between male age and semen volume in the last 33 years. The outcome of these studies are represented in Table 1. Most of the reports are based on infertility clinic (37.5%), andrology laboratories or assisted conception populations (25%), while the others used volunteers recruited from sperm banks or advertisements (20.8%) and epidemiological studies (16.7%). Among the 48 published research works discussed in this article from 1980 through 2013, most are carried out in U.S.A., Germany and China, while others include Australia, India, Korea, Demark and so on. Most of the studies have used sample size 1 000 (39.5%), a few used sample size between 500 and 1 000 subjects (22.9%) and 18 studies have used sample size less than 500 men (37.6%). Two reports from Spain[29] and Korea[35] have used an extraordinarily large sample size (20 411 and 22 249 respectively). Out of 48 reports, 41 studies (85.4%) have provided data about the age of subjects. Most of the reports revolve around comparative study between younger and aged subjects, while some reports generally described the change in semen volume with

#### Table 1

Male age and semen volume (data from 1980-2013).

increasing age. Although most of the studies have reported declines in semen volume with increased age; but, the number of reports with no alterations are also not negligible (31.2%). But most the reports are not ambiguous. Out of the 48 published articles, 29 have reported (60.4%) about decline in semen volume with male age, out of which again 10 reports depicted strong correlation with age [9,15,28,29,37-40,48,53]. Two of them[15,29], those examined age as a continuous variable, showed a decrease of 0.15%[15] to 0.5%[29] for increase in age by each year, even after adjustment for potential confounding by duration of abstinence. Several of the remaining studies claiming decline in semen volume with increasing age found large differences in semen volume (ranging from 0.6 - 0.9 mL) between the youngest and the oldest age group(s)[10,16,17,28]. However, only one of these studies adjusted for potential confounding by duration of abstinence. Among the four studies that found no relationship between age and volume[11,13,18,26], only one adjusted for duration of abstinence, by restricting analyses to less than 5 days of abstinence[11]. The one study[19] that reported a slight increase (0.01 mL/year) in volume with increased age, suggests that factor(s) related to time, other than aging, may also be responsible for the findings. Most of the studies listed in the following table did not adjust for potential confounding (e.g., smoking, type of infertility among clinic patients). Few studies adjusted are for abstinence, although there is good evidence in the literature that an increased duration of abstinence increases volume in a time-dependent fashion. A longer duration of abstinence among older men would likely to be bias towards finding no association or a positive association (an increase in volume with an increase in age). Overall, this may have contributed to a bias towards the null in results across studies. Four[15,17,29,31] of the five[11,15,17,29,31] studies that did

control for duration of abstinence showed a decrease in volume with increased age. The weight of the evidence suggests that there is a decrease in semen volume with increasing age, most notably among men over 50 years of age. In those studies that report a decrease, the relative decrease ranges between 3% and 30% for men less than 30 years old compared with men 50 years old, with most of these studies reporting a change of approximately 20%- 30%. The methodologically stronger studies[15,17,29] found more modest decreases of 3% - 22% comparing men in these age groups. This review may strongly evince that the trend of fathering in older age may come with risks for diminished sperm volume which is also attributed to environmetal, occupational and other lifestyle factors[57-60]. Future studies examining the relationship between male age and semen volume could improve the methodological quality of the existing studies by controlling the effects of potential confounding factors. As better biomarkers are now developed and are being used in epidemiological study designs, more knowledge may be gained regarding associations of age with semen volume and fertility in the future reports.
