# ON THE COVERING RADIUS OF SOME CODES OVER $R=Z_{2}+u Z_{2}$, WHERE $\mathbf{u}^{2}=0$ P. CHELLA PANDIAN \& C. DURAIRAJAN <br> Department of Mathematics, Bharathidasan University, Tiruchirappalli, Tamil Nadu, India 

#### Abstract

In this correspondence, we give lower and upper bounds on the covering radius of codes over the ring $\mathrm{R}=\mathrm{Z}_{2}+\mathrm{uZ} \mathrm{Z}_{2}$ where $\mathrm{u}^{2}=0$ with respect to different distance. We also determine the covering radius of various Repetition codes, Simplex codes (Type $\alpha$ and Type $\beta$ ) and their dual and give bounds on the covering radius for MacDonald codes of both types over R.

KEYWORDS: Covering Radius, Codes over Finite Rings, Simplex Codes, Hamming Codes

## 1 INTRODUCTION

In the last decade, there are many researchers doing research on code over finite rings. In particular, codes over $Z_{4}, Z_{2}+u Z_{2}$ where $\mathrm{u}^{2}=0$ received much attention $[1,2,3,4,5,9,11,12,14,16,17]$. The covering radius of binary linear codes were studied [6, 7]. Recently the covering radius of codes over $Z_{4}$ has been investigated with respect to Lee and Euclidean distances [1, 15]. In 1999, Sole et al gave many upper and lower bounds on the covering radius of a code over $\mathrm{Z}_{4}$ with different distances. In the recent paper [15], the covering radius of some particular codes over $\mathrm{Z}_{4}$ have been investigated. In this correspondence, we consider the ring $R=Z_{2}+u Z_{2}$ where $u^{2}=0$. In this paper, we investigate the covering radius of the Simplex codes (both types) and their duals, MacDonald codes and repetition codes over R. We also generalized some of the known bounds in [1]. A linear code $C$ of length $n$ over $R$ is an additive subgroup of $R^{n}$. An element of $C$ is called a codeword of $C$ and a generator matrix of $C$ is a matrix whose rows generate $C$. The Hamming weight $w_{H}(x)$ of a vector $x$ in $R^{n}$ is the number of non-zero components. The Lee weight for a codeword $x=\left(x_{1}, x_{2}, \ldots, x_{n}\right)$ is defined by $\mathrm{w}_{\mathrm{L}}(\mathrm{x})=\sum_{i=1}^{n} w_{L}\left(x_{i}\right)$, where $w_{L}\left(x_{i}\right)=\left\{\begin{array}{ll}0 & \text { if } \\ 1 & \text { if } \\ 2 & \text { if }\end{array} \quad \begin{array}{c}x_{i}=0 \\ x_{i}=1 \text { or } 1+u \\ x_{i}=u\end{array}\right.$

The Lee distance between the codewords x and $\mathrm{y} \in R^{n}$ is defined as $\mathrm{d}_{\mathrm{L}}(\mathrm{x}, \mathrm{y})=\mathrm{w}_{\mathrm{L}}(\mathrm{x}-\mathrm{y})$. The Euclidean weight is given by the relation $\mathrm{w}_{\mathrm{E}}(\mathrm{x})=\sum_{i=1}^{n} w_{E}\left(x_{i}\right)$, where $w_{E}\left(x_{i}\right)=\left\{\begin{array}{clc}0 & \text { if } & x_{i}=0 \\ 1 & \text { if } & x_{i}=1 \operatorname{or} 1+u \\ 4 & \text { if } & x_{i}=u\end{array}\right.$

The Euclidean distance between the codewords x and $\mathrm{y} \in R^{n}$ is defined as $\mathrm{d}_{\mathrm{E}}(\mathrm{x}, \mathrm{y})=\mathrm{w}_{\mathrm{E}}(\mathrm{x}-\mathrm{y})$.
A linear Gray map $\varphi$ from $R \rightarrow Z_{2}^{2}$ is defined by $\varphi(x+u y)=(y, x+y)$, for all $x+u y \in R$. The image $\varphi(C)$, of a linear code $C$ over $R$ of length $n$ by the Gray map, is a binary code of length $2 n$ with same cardinality [16]. The dual code $\mathrm{C}^{\perp}$ of C is defined as $\left\{\mathrm{x} \in \mathrm{R}^{\mathrm{n}} \mid \mathrm{x} . \mathrm{y}=0\right.$ for all $\left.\mathrm{y} \in \mathrm{C}\right\}$ where $\mathrm{x} . \mathrm{y}=\sum_{i=0}^{n} x_{i} y_{i}(\bmod 2) . \mathrm{C}$ is self-orthogonal if $\mathrm{C} \subseteq \mathrm{C}^{\perp}$ and C is self-dual if $\mathrm{C}=\mathrm{C}^{\perp}$. Two codes are said to be equivalent if one can be obtained from the other by
permuting the coordinates or changing the signs of certain coordinates or multiplying non-zero element in a fixed column. Codes differing by only a permutation of coordinates are called permutation-equivalent.

Any linear code $C$ over $R$ is equivalent to a code with generator matrix $G$ of the form

$$
G=\left[\begin{array}{ccc}
I_{k_{0}} & A & B  \tag{1.1}\\
0 & u I_{k_{1}} & u D
\end{array}\right],
$$

where $A, B$ and $D$ are matrices over $R$. Then the code $C$ contain all codewords $\left[\mathrm{v}_{0}, \mathrm{v}_{1}\right] G$, where $\mathrm{v}_{0}$ is a vector of length $k_{1}$ over $R$ and $v_{1}$ is a vector of length $k_{2}$ over $Z_{2}$. Thus $C$ contains a total of $4^{k_{1}} 2^{k_{2}}$ codewords. The parameters of C are given [ $\mathrm{n}, 4^{k_{1}} 2^{k_{2}}$, d] where d represents the minimum distance of C . In[11], we associate to the code C , two binary codes. The residue code $C_{1}$ is defined as $C_{1}=\left\{x \in Z_{2}^{n} \mid \exists \mathrm{y} \in \mathrm{Z}_{2}^{n}\right.$ and $\left.\mathrm{x}+\mathrm{uy} \in \mathrm{C}\right\}$ and the torsion code $C_{2}=\left\{x \in Z_{2}^{n} \mid u x \in C\right\}$. A vector $v$ is a 2-linear combination of the vectors $v_{1}, v_{2}, \ldots, v_{k}$ if $v=l_{1} v_{1}+\ldots+l_{k} v_{k}$ with $l_{i} \in Z_{2}$ for $1 \leq i \leq k$. A subset $S=\left\{v_{1}, v_{2}, \ldots, v_{k}\right\}$ of $C$ is called a 2 -basis for $C$ if for each $i=1,2, \ldots, k-1,2 v i$ is a 2-linear combination of $v_{i+1}, \ldots, v_{k}, 2 v_{k}=0, C$ is the 2-linear span of $S$ and $S$ is 2-linearly independent [18]. The number of elements in a 2-basis for C is the 2-dimension of C . It is easy to verify that the rows of the matrix

$$
B=\left[\begin{array}{ccc}
I_{K_{0}} & A & B  \tag{1.2}\\
u I_{k_{0}} & u A & u B \\
0 & u I_{k_{1}} & u D
\end{array}\right]
$$

form a 2-basis for the code C generated by G given in (1.1). A linear code C over R (over $\mathrm{Z}_{2}$ ) of length n , 2-dimension $k$, minimum distance $d_{H}$ and $d_{L}$ is called an [ $\left.n, k, d_{H}, d_{L}\right]\left(\left[n, k, d_{H}\right]\right.$ ) or simply an [ $\left.n, k\right]$ code. In this paper, we define the covering radius of codes over R with respect to different distances and in particular study the covering radius of Simplex codes of type $\alpha$ and $\beta$ namely, $\mathrm{S}_{k}^{\alpha}$ and $\mathrm{S}_{k}^{\beta}$ and their duals, MacDonald codes and repetition codes over R. Section 2 contains basic results for the covering radius of codes over R. Section 3 determines the covering radius of different types of repetition codes. Section 4 determines the covering radius of Simplex codes and its dual and finally section 5 determines the bounds on the covering radius of MacDonald codes.

## 2 COVERING RADIUS OF CODES

Let d be the general distance out of various possible distances (such as Hamming, Lee, and Euclidean). The covering radius of a code $C$ over R with respect to a general distance d is given by $\left.r_{d}(C)=\max _{u \in R^{n}} \min _{c \in C}\{d(c, u)\}\right\}$.

It is easy to see that $\mathrm{r}_{\mathrm{d}}(\mathrm{C})$ is the least positive integer $\mathrm{r}_{\mathrm{d}}$ such that $R^{n}=\bigcup_{c \in C} S_{r_{d}}(c)$ where $S_{r_{d}}(u)=\left\{v \in R^{n} \mid d(u, v) \leq r_{d}\right\}$ for any $u \in R^{\mathrm{n}}$. The translate $\mathrm{u}+\mathrm{C}=\{\mathrm{u}+\mathrm{c} \mid \mathrm{c} \in \mathrm{C}\}$ is called the coset of $C$ where $u \in R^{n}$. A vector of minimum weight in a coset is called a coset leader. The following propositions are straight forward generalization from [1].

## Proposition 2.1

The covering radius of $C$ with respect to the general distance $d$ is the largest minimum weight among all cosets.

## Proposition 2.2

Let C be a code over R and $\varphi(\mathrm{C})$ the generalized Gray map image of C . Then $\mathrm{r}_{\mathrm{L}}(\mathrm{C})=\mathrm{r}_{\mathrm{H}}(\varphi(\mathrm{C}))$.
Now, we give several lower and upper bounds on the covering radius of codes over R with respect to general weight. The proof of Proposition 2.3 and Theorem 2.4 being similar to the case of $Z_{4}$ [1], is omitted.

## Proposition 2.3 (Sphere-Covering Bounds)

For any code C of length n over R ,

$$
\frac{2^{2^{s-1_{n}}}}{|C|} \leq \sum_{i=0}^{r_{d}(C)}\binom{2^{s-1_{n}}}{i}
$$

We consider the two upper bounds on the covering radius of a code over R with respect to general weight. Let $C$ be a code over $R$ and let $s\left(C^{\perp}\right)=\left|\left\{i \mid A_{i}\left(C^{\perp}\right) \neq 0, i \neq 0\right\}\right|$ where $A_{i}\left(C^{\perp}\right)$ is the number of codewords of various possible distances i in $\mathrm{C}^{\perp}$.

## Theorem 2.4 (Delsarte Bound)

Let C be a code over R , then $\mathrm{r}_{\mathrm{d}}(\mathrm{C}) \leq \mathrm{s}\left(\mathrm{C}^{\perp}\right)$.
The following result of Mattson [6] is useful for computing covering radius of codes over rings generalized easily from codes over finite fields.

## Proposition 2.5 (Mattson)

If $C_{0}$ and $C_{1}$ are codes over $R$ generated by matrices $G_{0}$ and $G_{1}$ respectively and if $C$ is the code generated by $G=\left(\begin{array}{c|c}0 & G_{1} \\ \hline G_{0} & A\end{array}\right)$ then $\mathrm{r}_{\mathrm{d}}(\mathrm{C}) \leq \mathrm{r}_{\mathrm{d}}\left(\mathrm{C}_{0}\right)+\mathrm{r}_{\mathrm{d}}\left(\mathrm{C}_{1}\right)$ and the covering radius of D (concatenation of $\mathrm{C}_{0}$ and $\left.\mathrm{C}_{1}\right)$ satisfy the following $r_{d}(D) \geq r_{d}\left(C_{0}\right)+r_{d}\left(C_{1}\right)$, for all distances $d$ over $R$. Since the covering radius of $C$ generated by $G=[A \mid B]$ is greater than or equal to $r_{d}\left(C_{A}\right)+r_{d}\left(C_{B}\right)$ where $C_{A}$ and $C_{B}$ are codes generated by $A$ and $B$ respectively, this implies rd $(D) \geq r_{d}\left(C_{0}\right)+r_{d}\left(C_{1}\right)$ because $C_{1}$ is a subcode of the code generated $\left[G_{1} \mid A\right]$.

## 3 COVERING RADIUS OF REPETITION CODES

A q -ary repetition code C over a finite field $\mathrm{F}_{\mathrm{q}}=\left\{\alpha_{0}=0, \alpha_{1}=1, \alpha_{2}, \alpha_{3}, \ldots, \alpha_{\mathrm{q}-1}\right\}$ is an $[\mathrm{n}, 1, \mathrm{n}]$ code $C=\left\{\bar{\alpha} \mid \alpha \in F_{q}\right\}$, where $\bar{\alpha}=(\alpha, \alpha, \cdots, \alpha)$. The covering radius of C is $\left\lceil\frac{n(q-1)}{q}\right\rceil$ [13]. Using this, it can be seen easily that the covering radius of block (of size $n$ ) repetition code $[\mathrm{n}(\mathrm{q}-1), 1, \mathrm{n}(\mathrm{q}-1)]$ generated by $G=[\overbrace{11 \cdots 1}^{n} 1 \widetilde{\alpha}_{2} \widetilde{\alpha}_{2} \cdots \bar{\alpha}_{2} \widetilde{\alpha}_{3} \mathcal{\alpha}_{3} \cdots \bar{\alpha}_{3} \cdots \widetilde{\alpha}_{q-1}-\bar{\alpha}_{q-1} \cdots \bar{\alpha}_{q-1}^{n}]$ is $\left[\frac{n(q-1)^{2}}{q}\right]$ since it will be equivalent to a repetition code of length ( $q-1$ ) n . Consider the repetition code over R. There are two types of them of length n viz. unit repetition code $\mathrm{C}_{\beta}:[\mathrm{n}, 2, \mathrm{n}, \mathrm{n}]$ generated by $\mathrm{G}_{\beta}=[11 \ldots 1]$ and zero divisor repetition code $\mathrm{C}_{\alpha}:[\mathrm{n}, 1, \mathrm{n}, 2 \mathrm{n}]$ generated by $\mathrm{G}_{\alpha}=[\mathrm{uu} \ldots \mathrm{u}]$. With respect to the Hamming distance the covering radius of $\mathrm{C}_{\beta}$ is $\left\lceil\frac{n(q-1)}{q}\right\rceil$ but covering radius of $\mathrm{C}_{\alpha}$ is n .

The following result determines the covering radius with respect Lee distance and Euclidean distance.

## Theorem 3.1

$$
\mathrm{r}_{\mathrm{L}}\left(\mathrm{C}_{\alpha}\right)=\mathrm{n}, \mathrm{r}_{\mathrm{E}}\left(\mathrm{C}_{\alpha}\right)=2 \mathrm{n}, \mathrm{r}_{\mathrm{L}}\left(\mathrm{C}_{\beta}\right)=\mathrm{n} \text { and } \mathrm{r}_{\mathrm{E}}\left(\mathrm{C}_{\beta}\right)=\frac{3 n}{2}
$$

Proof. Note that $\varphi\left(\mathrm{C}_{\alpha}\right)$ is a binary repetition code of length 2 n hence $\mathrm{r}_{\mathrm{L}}\left(\mathrm{C}_{\alpha}\right)=\frac{2 n}{2}=\mathrm{n}$. Now by definition $\mathrm{r}_{\mathrm{E}}\left(\mathrm{C}_{\alpha}\right)=\max _{u \in R^{n}}\left\{d_{E}\left(x, C_{\alpha}\right)\right\}$. Let $\mathrm{x}=\overbrace{u u u \cdots u}^{\frac{n}{2}} \overbrace{000 \cdots 0}^{\frac{n}{2}} \in \mathrm{R}^{\mathrm{n}}$, then $\mathrm{d}_{\mathrm{E}}(\mathrm{x}, 0)=\mathrm{d}_{\mathrm{E}}(\mathrm{x}, \mathrm{u})=2 \mathrm{n}$. Thus $\mathrm{r}_{\mathrm{E}}\left(\mathrm{C}_{\alpha}\right) \geq 2 \mathrm{n}$. On the other hand if $\mathrm{x} \in \mathrm{R}^{\mathrm{n}}$ has a composition $\left(\omega_{0}, \omega_{1}, \omega_{2}, \omega_{3}\right)$, where $\sum_{i=0}^{3} w_{i}=n$ then $\mathrm{d}_{\mathrm{E}}(\mathrm{x}, \overline{0})=\mathrm{n}-\omega_{0}+3 \omega_{2}$ and $\mathrm{d}_{\mathrm{E}}(\mathrm{x}, \bar{u})$ $=\mathrm{n}-\omega_{2}+3 \omega_{0}$. Thus $\mathrm{d}_{\mathrm{E}}\left(\mathrm{x}, \mathrm{C}_{\alpha}\right)=\min \left\{\mathrm{n}-\omega_{0}+3 \omega_{2}, \mathrm{n}-\omega_{2}+3 \omega_{0}\right\} \leq \mathrm{n}+\omega_{0}+\omega_{2} \leq \mathrm{n}+\mathrm{n}=2 \mathrm{n}$. Hence $\mathrm{r}_{\mathrm{E}}\left(\mathrm{C}_{\alpha}\right)=2 \mathrm{n}$. Similar arguments can be used to show that $\mathrm{r}_{\mathrm{E}}\left(\mathrm{C}_{\beta}\right) \leq \frac{3 n}{2}$. To show that $\mathrm{r}_{\mathrm{E}}\left(\mathrm{C}_{\beta}\right) \geq \frac{3 n}{2}$, let $x=\overbrace{000 \cdots 0}^{t} \overbrace{111 \cdots 1}^{t} \overbrace{u u \cdots u}^{t} \cdots \overbrace{1+u 1+u \cdots 1+u}^{n-3 t} \in \mathrm{R}^{\mathrm{n}}$, where $\mathrm{t}=\left\lfloor\frac{n}{4}\right\rfloor$, then $\mathrm{d}_{\mathrm{E}}(\mathrm{x}, \overline{0})=\mathrm{n}+2 \mathrm{t}, \mathrm{d}_{\mathrm{E}}(\mathrm{x}, \overline{1})=4 \mathrm{n}-10 \mathrm{t}$, $\mathrm{d}_{\mathrm{E}}(\mathrm{x}, \bar{u})=\mathrm{n}+2 \mathrm{t}$ and $\mathrm{d}_{\mathrm{E}}(\mathrm{x}, \overline{1+u})=6 \mathrm{t}$. Thus $\mathrm{r}_{\mathrm{E}}\left(\mathrm{C}_{\beta}\right) \geq \min \{4 \mathrm{n}-10 \mathrm{t}, \mathrm{n}+2 \mathrm{t}, 6 \mathrm{t}\} \geq \frac{3 n}{2}$. The proof of $\mathrm{r}_{\mathrm{L}}\left(\mathrm{C}_{\beta}\right)=\mathrm{n}$ is simple so we omit it.

In order to determine the covering radius of Simplex and MacDonald codes over R, we need to define few block repetition codes over R and find their covering radius. To determine the covering radius of R block (three blocks each of size n) repetition code $\operatorname{BRep}_{\alpha}^{3 n}:[3 \mathrm{n}, 2,2 \mathrm{n}, 4 \mathrm{n}, 6 \mathrm{n}]$ generated by $G=[\overbrace{111 \cdots 1}^{n} \overbrace{u u \cdots u}^{n} \cdots \overbrace{1+u 1+u \cdots 1+u}^{n}]$ note that the code has constant Lee weight 4 n . Thus for $\mathrm{x}=11 \cdots 1 \in \mathrm{R}^{3 \mathrm{n}}$, we have $\mathrm{d}_{\mathrm{L}}\left(\mathrm{x}, \operatorname{BRep}{ }_{\alpha}^{3 n}\right)=3 \mathrm{n}$. Hence by definition, $r_{L}\left(\operatorname{BRep}_{\alpha}^{3 n}\right) \geq 3 n$. On the other hand, its Gray image $\varphi\left(\operatorname{BRep}_{\alpha}^{3 n}\right)$ is equivalent to binary linear code $[6 n, 2,4 n]$ with the generator matrix $\left(\begin{array}{cc|c|c|c}\overbrace{11}^{11} \cdots & 1 \\ \underbrace{2 n}_{2 n} \cdots & 1 & \overbrace{11} \cdots & \cdots & \overbrace{00}^{2 n} \\ 00 & \cdots & 0 & 0 & 0 \\ 11 & \cdots & 1\end{array}\right)$. Thus the covering radius $\mathrm{r}_{\mathrm{L}}\left(\operatorname{BRep}_{\alpha}^{3 n}\right) \leq \frac{4 n}{2}+\frac{2 n}{2}=3 \mathrm{n}$. Thus, we have $r_{L}\left(\operatorname{BRep}_{\alpha}^{3 n}\right)=3 n$. With respect Euclidean distance, it is clear that $r_{\mathrm{E}}\left(\operatorname{BRep}_{\alpha}^{3 n}\right) \geq \frac{3 n}{2}+2 n+\frac{3 n}{2}=5 n$. Let $\mathrm{x}=(\mathrm{u}|\mathrm{v}| \mathrm{w}) \in \mathrm{R}^{3 \mathrm{n}}$ with u , v and w have compositions $\left(\mathrm{r}_{0}, \mathrm{r}_{1}, \mathrm{r}_{2}, \mathrm{r}_{3}\right),\left(\mathrm{s}_{0}, \mathrm{~s}_{1}, \mathrm{~s}_{2}, s_{3}\right)$ and $\left(\mathrm{t}_{0}, \mathrm{t}_{1}, \mathrm{t}_{2}, \mathrm{t}_{3}\right)$ respectively such that sum of each component composition is $n$, then $d_{E}(x, \overline{0})=3 n-r_{0}+3 r_{2}-s_{0}+3 s_{2}-t_{0}+3 t_{3}, d_{E}\left(x, c_{1}\right)=3 n-r_{1}+3 r_{3}-s_{2}$ $+3 s_{0}-t_{3}+3 t_{1}, d_{E}\left(x, c_{2}\right)=3 n-r_{2}+3 r_{0}-s_{0}+3 s_{2}-t_{2}+3 t_{0}$ and $d_{E}\left(x, c_{3}\right)=3 n-r_{3}+3 r_{1}-s_{2}+3 s_{0}-t_{1}+3 t_{3}$. Thus $d_{\mathrm{E}}\left(\mathrm{x}, \operatorname{BRep}_{\alpha}^{3 n}\right) \leq 3 \mathrm{n}+\min \left\{3 \mathrm{r}_{2}+3 \mathrm{~s}_{2}+3 \mathrm{t}_{2}-\mathrm{r}_{0}-\mathrm{s}_{0}-\mathrm{t}_{0}, 3 \mathrm{r}_{3}+3 \mathrm{~s}_{0}+3 \mathrm{t}_{1}-\mathrm{r}_{1}-\mathrm{s}_{2}-\mathrm{t}_{3}, 3 \mathrm{r}_{0}+3 \mathrm{~s}_{2}+3 \mathrm{t}_{0}-\mathrm{r}_{2}-\mathrm{s}_{0}-\mathrm{t}_{2}, 3 \mathrm{r}_{1}+\right.$ $\left.3 \mathrm{~s}_{0}+3 \mathrm{t}_{3}-\mathrm{r}_{3}-\mathrm{s}_{2}-\mathrm{t}_{1}\right\} \leq 3 n+\frac{1}{2}\left\{2 \mathrm{n}+2 \mathrm{~s}_{0}+2 \mathrm{~s}_{2}\right\} \leq 5 \mathrm{n}$. Thus we have the following theorem.

## Theorem 3.2

$$
\mathrm{r}_{\mathrm{L}}\left(\operatorname{BRep}_{\alpha}^{3 n}\right)=3 \mathrm{n} \text { and } \mathrm{r}_{\mathrm{E}}\left(\operatorname{BRep}_{\alpha}^{3 n}\right)=5 \mathrm{n} .
$$

One can also define a R block (two blocks each of size $n$ ) repetition code $\operatorname{Brep}{ }_{\alpha}^{2 n}:[2 n, 2, n, 2 n, 4 n]$ generated by $G=[\overbrace{11 \cdots} 1 \overbrace{u u}^{n} \overbrace{\cdots}^{n} \overbrace{}^{n} u$. We have following theorem (its proof is similar to the proof of Theorem 3.2) so we omit it.

## Theorem 3.3

$$
\mathrm{r}_{\mathrm{L}}\left(\operatorname{BRep}_{\alpha}^{2 n}\right)=2 \mathrm{n} \text { and } \mathrm{r}_{\mathrm{E}}\left(\operatorname{BRep}_{\alpha}^{2 n}\right)=\frac{7 n}{2}
$$

Block code Brep ${ }_{\alpha}^{2 n}$ can be generalized to a block repetition code (two blocks of size m and n respectively)

$$
\operatorname{BRep}^{m+n}:[\mathrm{m}+\mathrm{n}, 2, \mathrm{~m}, \min \{2 \mathrm{~m}, \mathrm{~m}+2 \mathrm{n}\}, \min \{4 \mathrm{~m}, \mathrm{~m}+4 \mathrm{n}\}] \text { generated by } G=[\overbrace{11 \cdots 1}^{m} \overbrace{u u \cdots u}^{n} \overbrace{\mathrm{n}}^{n}] \text {. Theorem }
$$ 3.3 can be easily generalized using similar arguments to the following.

## Theorem 3.4

$$
r_{L}\left(\text { BRep }^{m+n}\right)=m+n \text { and } r_{E}\left(\text { BRep }^{m+n}\right)=2 n+\frac{3 m}{2}
$$

## 4 SIMPLEX CODES OF TYPE $\alpha$ AND $\beta$ OVER $\boldsymbol{R}$

Quaternary simplex codes of type $\alpha$ and $\beta$ have been recently studied in [2]. Type $\alpha$ Simplex code $S_{k}^{\alpha}$ is a linear code over $R$ with parameters [ $\left.2^{2 \mathrm{k}}, 2 \mathrm{k}, 2^{2 \mathrm{k}-1}, 2^{2 \mathrm{k}}, 3.2^{2 \mathrm{k}-1}\right]$ and an inductive generator matrix given by

$$
G_{k}^{\alpha}=\left[\begin{array}{c|c|c|c}
00 \cdots 0 & 11 \cdots 1 & u u \cdots u & 1+u 1+u \cdots 1+u  \tag{4.1}\\
\hline G_{k-1}^{\alpha} & G_{k-1}^{\alpha} & G_{k-1}^{\alpha} & G_{k-1}^{\alpha}
\end{array}\right]
$$

with $G_{1}^{\alpha}=\left[\begin{array}{lll}0 & 1 & u \\ 1 & 1+u\end{array}\right]$. The dual code of $S_{k}^{\alpha}$ is a $\left[2^{2 \mathrm{k}}, 2^{2 \mathrm{k}+1}-2 \mathrm{k}\right]$ code. Type simplex code $S_{k}^{\beta}$ is a punctured version of $S_{k}^{\alpha}$ with parameters $\left[2^{\mathrm{k}-1}\left(2^{\mathrm{k}}-1\right), 2 \mathrm{k}, 2^{2(\mathrm{k}-1)}, 2^{(\mathrm{k}-1)}\left(2^{\mathrm{k}}-1\right), 2^{\mathrm{k}}\left(3.2^{\mathrm{k}-2}-1\right)\right]$ and an inductive generator matrix given by

$$
\begin{align*}
& G_{2}^{\beta}=\left[\begin{array}{cccc|c|c}
1 & 1 & 1 & 1 & 0 & u \\
\hline 1 & 1 & u & 1+u & 1 & 1
\end{array}\right]  \tag{4.2}\\
& \text { and for } k>2 G_{k}^{\beta}=\left[\begin{array}{cc|cc|c}
11 \cdots 1 & 00 \cdots 0 & u u \cdots u \\
\hline G_{k-1}^{\alpha} & G_{k-1}^{\beta} & G_{k-1}^{\beta}
\end{array}\right] \tag{4.3}
\end{align*}
$$

where $G_{k-1}^{\alpha}$ is the generator matrix of $S_{k-1}^{\alpha}$. For details the reader is refereed to [2]. The dual code of $S_{k}^{\beta}$ is a $\left[2^{\mathrm{k}-1}\left(2^{\mathrm{k}}-1\right), 2^{2 \mathrm{k}}-2^{\mathrm{k}}-2 \mathrm{k}\right]$ type $\alpha$ code with minimum Lee weight $d_{\mathrm{L}}=3$.

## Theorem 4.1

$$
2^{2 \mathrm{k}} \leq r_{\mathrm{L}}\left(S_{k}^{\alpha}\right) \leq 2^{2 \mathrm{k}}+1 \text { and } r_{\mathrm{E}}\left(S_{k}^{\alpha}\right) \leq \frac{5.4^{k}+5}{3}
$$

Proof. Let $x=11 \ldots . .1 \in \mathrm{R}^{\mathrm{n}}$, we have $d_{\mathrm{L}}\left(x, S_{k}^{\alpha}\right)=2^{2 \mathrm{k}}$. By definition, $r_{\mathrm{L}}\left(S_{k}^{\alpha}\right) \geq 2^{2 \mathrm{k}}$. To find the upper bound, by equation 4.1, the result of Mattson for finite rings and using Theorem 3.2, we get

$$
\begin{aligned}
r_{\mathrm{L}}\left(S_{k}^{\alpha}\right) & \leq r_{\mathrm{L}}\left(S_{k-1}^{\alpha}\right)+r_{\mathrm{L}}(<\overbrace{11 \cdots 1}^{2^{2(k-1)}} \overbrace{u u \cdots u}^{2^{2(k-1)}} \overbrace{1+u 1+u \cdots 1+u}>) \\
& =r_{\mathrm{L}}\left(S_{k-1}^{\alpha}\right)+3.2^{2(k-1)} \\
& =3.2^{2(k-1)}+3.2^{2(k-2)}+3.2^{2(k-3)}+\ldots .+3.2^{2.2}+3.2^{2.1}+r_{\mathrm{L}}\left(S_{1}^{\alpha}\right)
\end{aligned}
$$

$r_{\mathrm{L}}\left(S_{k}^{\alpha}\right) \leq 2^{2 \mathrm{k}}+1\left(\right.$ since $\left.r_{\mathrm{L}}\left(S_{1}^{\alpha}\right)=5\right)$. Thus $2^{2 \mathrm{k}} \leq r_{\mathrm{L}}\left(S_{k}^{\alpha}\right) \leq 2^{2 \mathrm{k}}+1$.
Similar arguments can be used to show $r_{\mathrm{E}}\left(S_{k}^{\beta}\right) \leq 5\left(4^{(\mathrm{k}-1)}+4^{(\mathrm{k}-2)}+4^{(\mathrm{k}-3)}+\ldots+4^{1}+1\right)-\frac{11}{2}+r_{\mathrm{E}}\left(S_{1}^{\alpha}\right)$.
$r_{\mathrm{E}}\left(S_{k}^{\alpha}\right) \leq \frac{5.4^{k}+5}{3}$ (since $\left.r_{\mathrm{E}}\left(S_{1}^{\alpha}\right)=8\right)$. Similar arguments will compute the covering radius of Simplex codes of type $\beta$. We provide an outline of the proof.

## Theorem 4.2

$$
r_{\mathrm{L}}\left(S_{k}^{\beta}\right) \leq 2^{\mathrm{k}-1}\left(2^{\mathrm{k}}-1\right)-1 \text { and } r_{\mathrm{E}}\left(S_{k}^{\beta}\right) \leq \frac{5.4^{k}-6.2^{k}-8}{6}
$$

Proof. By equation 4.3, Proposition 2.5 and Theorem 3.4, we get

$$
\begin{aligned}
r_{\mathrm{L}}\left(S_{k}^{\beta}\right) & \leq r_{\mathrm{L}}\left(S_{k-1}^{\beta}\right)+r_{\mathrm{L}}(<\overbrace{11 \cdots 1}^{4^{(k-1)}} \overbrace{u u \cdots u}^{2^{(2 k-3)}-2^{(k-2)}}>) \\
& =r_{\mathrm{L}}\left(S_{k-1}^{\beta}\right)+2^{(2 k-2)}+2^{(2 k-3)}-2^{(k-2)} \\
& \leq\left(2^{(2 k-2)}+2^{(2 k-4)}+\ldots+2^{4}\right)+\left(2^{(2 k-3)}+2^{(2 k-5)}+\ldots+2^{3}\right)-\left(2^{(k-2)}+2^{(k-3)}+\ldots+2\right)+r_{\mathrm{L}}\left(S_{2}^{\beta}\right)
\end{aligned}
$$

Thus $r_{\mathrm{L}}\left(S_{k}^{\beta}\right) \leq 2^{\mathrm{k}-1}\left(2^{\mathrm{k}}-1\right)-1\left(\right.$ since $\left.r_{\mathrm{L}}\left(S_{2}^{\beta}\right)=5\right)$. Similarly, by using Theorem 3.4, we derive

$$
\begin{aligned}
& r_{\mathrm{E}}\left(S_{k}^{\beta}\right) \leq \frac{3}{2}\left(4^{(\mathrm{k}-1)}+4^{(\mathrm{k}-2)}+\ldots+4^{2}\right)+\left(4^{(\mathrm{k}-1)}+4^{(\mathrm{k}-2)}+\ldots+4^{2}\right)-2\left(2^{\mathrm{k}-2}+2^{\mathrm{k}-3}+\ldots+2\right)+r_{\mathrm{E}}\left(S_{2}^{\beta}\right) \\
& r_{\mathrm{E}}\left(S_{k}^{\beta}\right) \leq \frac{5.4^{k}-6.2^{k}-8}{6}\left(\text { since } r_{\mathrm{E}}\left(S_{2}^{\beta}\right)=8\right) .
\end{aligned}
$$

## Theorem 4.3

$$
r_{L}\left(S_{k}^{\alpha \perp}\right)=1, r_{L}\left(S_{k}^{\beta \perp}\right)=2, r_{E}\left(S_{k}^{\alpha \perp}\right) \leq 4 \text { and } r_{E}\left(S_{k}^{\beta \perp}\right) \leq 4
$$

Proof. By Delsarte Bound, $r_{L}\left(S_{k}^{\alpha \perp}\right) \leq 1$ and $r_{L}\left(S_{k}^{\beta \perp}\right) \leq 2$. Thus equality follows in the first case. For second case, note that $r_{L}\left(S_{k}^{\beta \perp}\right) \neq 1$, by sphere covering bound. The result for Euclidean distance follows from Delsarte bound.

## 5 MACDONALD CODES CODES OF TYPE $\alpha$ AND $\beta$ OVER R

The $q$-ary MacDonald code $M_{k, t}(q)$ over the finite field $\mathrm{F}_{q} \quad$ is a unique $\left[\frac{q^{k}-q^{t}}{q-1}, k, q^{k-1}-q^{t-1}\right]$ code in which every nonzero codeword has weight either $q^{k-1}$ or $q^{k-1}-q^{t-1}$ [10]. In [8], authors have defined the MacDonald codes over $R$ using the generator matrices of simplex codes. For $1 \leq t \leq k-1$, let $G_{k, t}^{\alpha}\left(G_{k, t}^{\beta}\right)$ be the matrix obtained from $G_{k,}^{\alpha}\left(G_{k,}^{\beta}\right)$ by deleting columns corresponding to the columns of

$$
\begin{equation*}
G_{t}^{\alpha}\left(G_{t}^{\beta}\right) . \text { i. e, } G_{k, t}^{\alpha}=\left[G_{k}^{\alpha} \backslash \frac{0}{G_{t}^{\alpha}}\right] \tag{5.1}
\end{equation*}
$$

$$
\text { and } G_{k, t}^{\beta}=\left[G_{k}^{\beta} \backslash \frac{0}{G_{t}^{\beta}}\right]
$$

where $[A \backslash B]$ denotes the matrix obtained from the matrix $A$ by deleting the columns of the matrix $B$ and $\mathbf{0}$ in 5.1 (respectively $(5.2)$ ) is a $(k-t) \times 2^{2 t}$ (respectively $\left.(k-t) \times 2^{t} 1^{1}\left(2^{\mathrm{t}}-1\right)\right)$ zero matrix. The code $M \underset{k, t}{\alpha}:\left[2^{2 k}-2^{2 t}, 2 k\right]\left(M \underset{k, t}{\beta}:\left[\left(2^{k-1}-2^{t-1}\right)\left(2^{k}+2^{t}-1\right), 2 k\right]\right)$ generated by the matrix $G_{k, t}^{\alpha}\left(G_{k, t}^{\beta}\right)$ is the punctured code of $S_{k}^{\alpha}\left(S_{k}^{\beta}\right)$ and is called a MacDonald code of type $\alpha(\beta)$. Next Theorem provides basic bounds on the covering radius of MacDonald codes.

## Theorem 5.1

$$
\begin{aligned}
& r_{L}\left(M_{k, t}^{\alpha}\right) \leq 4^{k}-4^{r}+r_{L}\left(M_{r, t}^{\alpha}\right) \text { for } \mathrm{t}<\mathrm{r} \leq \mathrm{k} \\
& r_{E}\left(M_{k, t}^{\alpha}\right) \leq \frac{5}{3}\left(4^{k}-4^{r}\right)+r_{E}\left(M_{r, t}^{\alpha}\right) \text { for } \mathrm{t}<\mathrm{r} \leq \mathrm{k}
\end{aligned}
$$

Proof. By Theorem 3.2,

$$
\begin{aligned}
r_{L}(M \underset{k, t}{\alpha}) & \leq 3.2^{(2 k-2)}+r_{L}\left(M_{k-1, t}^{\alpha}\right) \\
& \leq 3.2^{(2 k-2)}+3.2^{(2 k-4)}+\ldots+3.2^{2 r}+r_{L}\left(M_{r, t}^{\alpha}\right), \mathrm{k} \geq \mathrm{r}>\mathrm{t} \\
& =4^{k}-4^{r}+r_{L}\left(M_{r, t}^{\alpha}\right)
\end{aligned}
$$

Similar arguments holds for $r_{E}\binom{M}{k, t}$. Similarly using equation 5.2, Proposition 2.5 and Theorem 3.4, following bounds can be obtained for type $\beta$ MacDonald code.

## Theorem 5.2

$$
r_{L}\left(M_{k, t}^{\beta}\right) \leq 2^{(k-1)}\left(2^{k}-1\right)+2^{(r-1)}\left(1-2^{r}\right)+r_{L}\left(M_{r, t}^{\beta}\right) \text { for } \mathrm{t}<\mathrm{r} \leq \mathrm{k}
$$

$$
r_{E}\left(M_{k, t}^{\beta}\right) \leq \frac{2^{k}\left(5.2^{k}-6\right)+2^{r}\left(6-5.2^{r}\right)}{6}+r_{E}\left(M_{r, t}^{\beta}\right) \text { for } \mathrm{t}<\mathrm{r} \leq \mathrm{k}
$$

## ACKNOWLEDGEMENTS

The first author would like to gratefully acknowledge the UGC-RGNF [Rajiv Gandhi National Fellowship (No. F. 14-2(SC)/2010/SA-III)], New Delhi for providing fellowship and the second author was supported by a grant (SR/S4/MS: 588/09) for the Department of Science and Technology, New Delhi.
