# OPTIMAL CONTROL UNDER PARTIAL OBSERVATIONS AND STOCHASTIC UNIFORM OBSERVABILITY 

Ungureanu Viorica Mariela, dr., Constantin Brancuşi University

#### Abstract

This paper discuss linear quadratic control problem for stochastic differential systems with partial observations. Following [4] and using the results in [8] concerning the Riccati equation, we apply the well known separation principle to obtain a solution of the optimal control problem considered.

## 1. Optimal control under partial observations

Let $\mathrm{H}, \mathrm{U}, \mathrm{V}, \operatorname{dim}(\mathrm{V})<\infty$ be separable real Hilbert spaces. Throughout this section we will assume that the next hypothesis are satisfied:
Throughout this chapter we assume the following hypotheses:
(G1) $U(t, s)$ is a strong evolution operator generated by the family $\mathrm{A}(\mathrm{t}), \mathrm{t} \in[0, \infty)$; there exists a sequence $\left\{\mathrm{A}_{\mathrm{n}}\right\}_{\mathrm{n} \in \mathbf{N}} \subset \mathrm{C}_{\mathrm{s}}([0, \infty), \mathrm{L}(\mathrm{H}))$ such that for every $\mathrm{n} \in \mathbf{N}$, the family $\left\{A_{n}(t)\right\}_{\unrhd \geq 0}$ generates the strong evolution operator $U_{n}(t, s)$ and $\mathrm{U}_{\mathrm{n}}(\mathrm{t}, \mathrm{s}) \mathrm{x} \underset{\mathrm{n} \rightarrow \infty}{\rightarrow} \mathrm{U}(\mathrm{t}, \mathrm{s}) \mathrm{x}, \mathrm{x} \in \mathrm{H}$ uniformly on bounded subsets of $\Delta$. The families $A^{*}(t), \mathrm{A}_{\mathrm{n}}^{*}(\mathrm{t}), \mathrm{n} \in \mathbf{N}, \mathrm{t} \in[0, \infty)$ satisfy the hypothesis (G1) and we will say that G1 (A*) holds.
(G2): $\mathrm{B} \in \mathrm{C}_{\mathrm{b}}\left(\mathbf{R}_{+}, \mathrm{L}(\mathrm{U}, \mathrm{H})\right), \mathrm{B}^{*} \in \mathrm{C}_{\mathrm{b}}\left(\mathbf{R}_{+}, \mathrm{L}(\mathrm{H}, \mathrm{U})\right), \mathrm{C} \in \mathrm{C}_{\mathrm{b}}\left(\mathbf{R}_{+}, \mathrm{L}(\mathrm{H}, \mathrm{V})\right), \mathrm{C}^{*} \in \mathrm{C}_{\mathrm{b}}\left(\mathbf{R}_{+}, \mathrm{L}(\mathrm{V}, \mathrm{H})\right)$ , $\mathrm{N}, \mathrm{G}, \mathrm{G}^{*} \in \mathrm{C}_{\mathrm{b}}\left(\mathbf{R}_{+}, \mathrm{L}(\mathrm{H})\right), \quad \overline{\mathrm{V}} \in \mathrm{C}([0, \infty), \mathrm{L}(\mathrm{V})), \mathrm{V}(\mathrm{t})$ is nonsingular for all $t \in[0, \infty)$ and $\mathrm{K} \in \mathrm{C}_{\mathrm{b}}\left(\mathbf{R}_{+}, \mathrm{L}(\mathrm{U})\right.$ is uniformly positive, that is there exists $\delta>0$ such that $\mathrm{K}(\mathrm{t}) \geq \delta \mathrm{I}$, for all $t \in \mathbf{R}_{+}$.
We consider the following stochastic system with control and partial observations
(1) $d y(t)=A(t) y(t) d t+B(t) u(t) d t+G(t) d w(t)$,

$$
\mathrm{y}(0)=\mathrm{y}_{0} \in \mathrm{~L}_{\mathrm{s}}^{2}(\mathrm{H}) ;
$$

(2) $d z(t)=C(t) y(t) d t+\bar{V}(t) d v(t), z(0)=0$,
where $\mathrm{w}(\mathrm{t}), \mathrm{v}(\mathrm{t}), \mathrm{t} \geq 0$ are real valued Wiener processes and $y_{0}$ is Gaussian with mean $m_{0}$ and covariance $Q_{0}$ and $y_{0}, \mathrm{w}(\mathrm{t}, \mathrm{v}(\mathrm{t}), \mathrm{t} \geq 0$ are mutually independent. We also introduce the cost functional
(3)
$J(u)=\varlimsup_{t \rightarrow \infty} \frac{1}{t} E \int_{0}^{t}\|N(s) y(s)\|^{2}+\langle K(s) u(s), u(s)\rangle d s$

Our problem is to minimize $J(u)$ over a class of admissible controls $u(t)$, which are adapted to the $\sigma$-algebra generated by the observations $\mathrm{z}(\mathrm{s}), \mathrm{s} \in[0, \mathrm{t}]$. We will define the set of admissible controls later. Now, we recall some basic results on filtering theory. Let $Z_{t}$ be the $\sigma-$ algebra generated by $\mathrm{z}(\mathrm{s}), \mathrm{s} \in[0, \mathrm{t}]$ and let us consider the system
(4) $\mathrm{dy}(\mathrm{t})=\mathrm{A}(\mathrm{t}) \mathrm{y}(\mathrm{t}) \mathrm{dt}+\mathrm{G}(\mathrm{t}) \mathrm{dw}(\mathrm{t}), \mathrm{y}(0)=\mathrm{y}_{0}$
(5) $\mathrm{dz}(\mathrm{t})=\mathrm{Cy}(\mathrm{t}) \mathrm{dt}+\mathrm{V}(\mathrm{t}) \mathrm{dv}(\mathrm{t}), \mathrm{z}(0)=0$

The filtering problem consists in estimating the state $y(t)$ based on the observation process $\mathrm{z}(\mathrm{s}), 0 \leq \mathrm{s} \leq \mathrm{t}$. The most popular, optimal in the mean square sense, filtering estimator of $\mathrm{y}(\mathrm{t})$ is its projection onto $\mathrm{L}^{2}\left(\Omega, \mathrm{Z}_{\mathrm{t}}, \mathrm{P}, \mathrm{H}\right)$. This estimator is called the best global estimator of $y$ given $\mathrm{z}(\mathrm{s}), 0 \leq \mathrm{s} \leq \mathrm{t}$ and is equal to the conditional expectation $\mathrm{E}\left[\mathrm{y}(\mathrm{t}) \mid \mathrm{Z}_{\mathrm{t}}\right] \quad$ [6]. The conditional expectation, as a function of $z(s), s \in[0, t]$, may have too complicated structure. Therefore, especially in engineering applications, it makes sense to use a linear function $\hat{y}(t)$ of $z(s), s \in[0, t]$, minimizing the mean square error $E\|y(t)-\hat{y}(t)\|^{2} \quad$ in a class of linear filtering estimates. Then we define below the best affine estimator of $y(t)$.
Let $T>0$ be fixed and let $\mathrm{z} \in \mathrm{C}\left([0, \mathrm{~T}], \mathrm{L}^{2}(\Omega, \mathrm{~F}, \mathrm{P}, \mathrm{V})\right), \mathrm{y} \in \mathrm{L}^{2}(\Omega, \mathrm{P}, \mathrm{H})$. We denote by $\mathrm{H}_{\mathrm{z}}^{\mathrm{t}}$ the closure in $L^{2}(\Omega, \mathrm{P}, \mathrm{H})$ of the linear space generated by the set $\left\{\mathrm{x}+\mathrm{L}\left(\mathrm{z}\left(\mathrm{s}_{\mathrm{j}}\right)\right), \mathrm{x} \in \mathrm{H}, \mathrm{L} \in \mathrm{L}(\mathrm{V}, \mathrm{H}), \mathrm{s}_{\mathrm{j}} \in[0, \mathrm{t}]\right\}$. Obviously $\mathrm{H}_{\mathrm{z}}^{\mathrm{t}} \quad$ is the analogue of the Hilbert space $H_{y}$ defined in the time invariant case and it is a Hilbert subspace of $L^{2}(\Omega, P, H)$. If $P_{z}^{t}$ denotes the projection on $\mathrm{L}^{2}(\Omega, \mathrm{P}, \mathrm{H})$ upon $\mathrm{H}_{\mathrm{z}}^{\mathrm{t}}$ then $\mathrm{P}_{\mathrm{z}}^{\mathrm{t}}(\mathrm{y})$ is called the best affine estimator of $\mathrm{y} \in \mathrm{L}^{2}(\Omega, \mathrm{P}, \mathrm{H})$ given $\{\mathrm{z}(\mathrm{s}), 0 \leq \mathrm{s} \leq \mathrm{t}\}$. As in the discrete-time case we note that if we set $\bar{z}(t)=z(t)-E(z(t))$, then $H_{z}^{t}=H_{z}^{t}$.

If $H_{0}=\left\{y \in L^{2}(\Omega, P, H), E(y)=0\right\} \quad$ is the Hilbert subspace of $L^{2}(\Omega, P, H)$ and $\mathrm{H}_{0, \overline{\mathrm{z}}}^{\mathrm{t}} \quad$ is the closure in $\mathrm{L}^{2}(\Omega, \mathrm{P}, \mathrm{H})$ of the linear space generated by the set $\left\{\mathrm{L}\left(\mathrm{z}\left(\mathrm{s}_{\mathrm{j}}\right)\right), \mathrm{L} \in \mathrm{L}(\mathrm{V}, \mathrm{H}), \mathrm{s}_{\mathrm{j}} \in[0, \mathrm{t}]\right\}$ then $\mathrm{P}_{0, \overline{\mathrm{z}}}^{\mathrm{t}}(\mathrm{y})$ will denote the projection on $\mathrm{L}^{2}(\Omega, \mathrm{P}, \mathrm{H})$ upon $\mathrm{H}_{0, \bar{z}}^{\mathrm{t}}$. Obviously $\mathrm{H}_{0, \bar{z}}^{\mathrm{t}} \subset \mathrm{H}_{\mathrm{z}}^{\mathrm{t}}$. Then $\mathrm{P}_{0, \overline{\mathrm{z}}}^{\mathrm{t}}(\mathrm{y})$ is called the best linear estimator of $\mathrm{L}^{2}(\Omega, \mathrm{P}, \mathrm{H}) y$ given $\quad\{\overline{\mathrm{z}}(\mathrm{s}), 0 \leq \mathrm{s} \leq \mathrm{t}\} \quad$. It is clear that $\quad \mathrm{P}_{\mathrm{z}}^{\mathrm{t}}(\mathrm{y})=\mathrm{E}(\mathrm{y})+\mathrm{P}_{0, \mathrm{z}}^{\mathrm{t}}-(\mathrm{y}) \quad$ and consequently the problem of finding the best affine estimator reduces to that of finding the best linear estimator [7]. We note here that the linear estimates are easier to calculate, but unlike the best global estimates they need not always exist.

It is known that if $\mathrm{y} \in \mathrm{L}^{2}(\Omega, \mathrm{P}, \mathrm{H}), \mathrm{z} \in \mathrm{L}^{2}(\Omega, \mathrm{P}, \mathrm{V})$ are Gaussian random variables and the best linear estimate of $y$ given $z$ exists, then it coincides with the best global estimate [2].

As in the discrete-time case, the filtering problem for (4), (5) is to find the best affine estimate $\hat{y}(t)=P_{z}^{\mathrm{t}}(\mathrm{y}), \mathrm{t} \geq 0$. It is well known [2], [1], [7] that, because of the Gaussian property of the processes, the best affine estimate of the solution $y(t)$ of (4), (5) coincides with the best global estimator $E\left[y(t) \mid Z_{t}\right]$. Moreover, it is the unique mild solution of
(6) $d \hat{y}(\mathrm{t})=\mathrm{A}(\mathrm{t}) \hat{\mathrm{y}}(\mathrm{t}) \mathrm{dt}+\mathrm{P}(\mathrm{t}) \mathrm{C}^{*}(\mathrm{t})\left[\overline{\mathrm{V}}(\mathrm{t}) \overline{\mathrm{V}}^{*}(\mathrm{t})\right]^{-1} \mathrm{~d} \eta(\mathrm{t})$,
(7) $\hat{y}(0)=E\left(y_{0}\right)$,
where $\eta$ is the innovation process defined by
(8) $\mathrm{d} \mathrm{\eta}(\mathrm{t})=\mathrm{dz}(\mathrm{t})-\mathrm{C}(\mathrm{t}) \hat{\mathrm{y}}(\mathrm{t}) \mathrm{dt}$
and $P(t)$ is the covariance of the error process $e(t)=y(t)-\hat{y}(t)$. A rather surprising properties are the following: the innovation process $\eta(t)$ is a finite dimensional Wiener process with the covariance $\mathrm{t} \overline{\mathrm{V}}(\mathrm{t}) \overline{\mathrm{V}}(\mathrm{t})^{*}$ relative to the $\sigma$-algebra $\mathrm{Z}_{\mathrm{t}} ; \quad \mathrm{H}_{0, \bar{z}}^{\mathrm{t}}=\mathrm{H}_{0, \bar{\eta}}^{\mathrm{t}} \quad[2]$, [7]. Also it is known that the covariance of the error process is the unique mild solution of the following Riccati equation [2], [5]
(9) $P^{\prime}(\mathrm{t})=\mathrm{A}(\mathrm{t}) \mathrm{P}(\mathrm{t})+\mathrm{P}(\mathrm{t}) \mathrm{A}^{*}(\mathrm{t})+\mathrm{G}(\mathrm{t}) \mathrm{G}^{*}(\mathrm{t})-\mathrm{P}(\mathrm{t}) \mathrm{C}^{*}(\mathrm{t})\left[\overline{\mathrm{V}}(\mathrm{t}) \overline{\mathrm{V}}^{*}(\mathrm{t})\right]^{-1} \mathrm{C}(\mathrm{t}) \mathrm{P}(\mathrm{t})$
(10) $\mathrm{P}(0)=\mathrm{P}_{0}=\operatorname{cov}\left(\mathrm{e}_{0}, \mathrm{e}_{0}\right), \mathrm{e}_{0}=\mathrm{y}_{0}-\overline{\mathrm{y}}_{0}$.

The next result shows that, under stabilizability conditions, the above Riccati equation has a bounded on $\mathbf{R}_{+}$solution. We recall here that the pair $\left\{\mathrm{A}^{*}: \mathrm{C}^{*}\right\}$ is stabilizable iff there exists $\mathrm{F} \in \mathrm{C}_{\mathrm{b}}([0, \infty), \mathrm{L}(\mathrm{H}, \mathrm{V}))$ such that $\left\{\mathrm{A}^{*}+\mathrm{C}^{*} \mathrm{~F}\right\}$ is uniformly exponentially stable.

Theorem 1 [4] Assume $\left\{\mathrm{A}^{*}: \mathrm{C}^{*}\right\}$ is stabilizable. The solution $P(t)$ of (9)-(10) is bounded on $\mathbf{R}_{+}$.

Returning to the quadratic control problem, we now define the class of admissible controls $\mathcal{U}$. Let $\Gamma_{\mathrm{t}}$ be the $\sigma$ - algebra generated by $\eta(\mathrm{s}), \mathrm{s} \in[0, \mathrm{t}]$, where $\eta$ is the innovation process given by (8).

Following [4], [5], [7] we that $V$ is the set of all controls $u \in L_{\text {loc }}^{2}([0, \infty) \times \Omega, U)$ that are $F_{t}$ - adapted and satisfy the conditions $u(t) \in L^{2}\left(\Omega, Z_{t}, P, H\right) \cap L^{2}\left(\Omega, \Gamma_{t}, P, H\right)$ for almost all $t$, $\varlimsup_{t \rightarrow \infty} \frac{1}{t} E \int_{0}^{t}\|u(s)\|^{2} d s<\infty, \quad \sup _{t \geq 0} E\|y(s)\|^{2}<\infty$.

If $u \in \mathcal{V}$, we associate to the system (6), (7) the following control system
(11) $d \hat{y}(t)=A(t) \hat{y}(t) d t+B(t) u(t) d t+P(t) C^{*}(t)\left[\overline{\mathrm{V}}(\mathrm{t}) \overline{\mathrm{V}}^{*}(\mathrm{t})\right]^{-1} d \eta(\mathrm{t})$,
(12) $\hat{y}(0)=E\left(y_{0}\right)$

Denoting by $\hat{y}_{u}$ the solution of the above system, then $\hat{y}-\hat{y}_{u}$ is the unique solution of
the system
(13) $d x(t)=A(t) x(t) d t+B(t) u(t) d t, x(0)=0$.

Choosing the same control $u$, we consider the unique mild solutions $y_{u}$ and $y$ of (4) and (1) respectively, and we see that $y-y_{u}$ is also the unique mild solution (13). Therefore $y-y_{u}=\hat{y}-\hat{y}_{u}$ and $y_{u}(t)-\hat{y}_{u}(t)=e(t)$. An easy computation shows that $E\left\|N(t) y_{u}(t)\right\|^{2}=\operatorname{TrN}(t) \operatorname{cov}(e(t), e(t)) N^{*}(t)+2 E\left\langle N(t) \hat{y}_{u}(t), e(t)\right\rangle+E\left\|N(t) \hat{y}_{u}(t)\right\|^{2}$.
If $U(t, s)$ is the evolution operator generated by $A$ then

$$
\hat{\mathrm{y}}_{\mathrm{u}}(\mathrm{t})=\mathrm{U}(\mathrm{t}, \mathrm{r}) \overline{\mathrm{y}}_{0}+\int_{0}^{\mathrm{t}} \mathrm{U}(\mathrm{t}, \mathrm{r}) \mathrm{B}(\mathrm{r}) \mathrm{u}(\mathrm{r}) \mathrm{dr}+
$$

$\int_{0}^{t} U(t, r) P(r) C^{*}(r)\left[V(r) V^{*}(r)\right]^{-1} d \eta(r)=T_{1}+T_{2}+T_{3}$.
We note that $\mathrm{T}_{3} \in \mathrm{H}_{0, \bar{\eta}}^{\mathrm{t}} \quad$ and $\quad \mathrm{H}_{0, \bar{\eta}}^{\mathrm{t}}=\mathrm{H}_{0, \bar{z}}^{\mathrm{t}} \subset \mathrm{H}_{\mathrm{z}}^{\mathrm{t}}$. Since $\mathrm{e}(\mathrm{t}) \in\left(\mathrm{H}_{\mathrm{z}}^{\mathrm{t}}\right)^{\perp} \quad$ we deduce $E\left\langle T_{3}, e(t)\right\rangle=0$. Also $\quad T_{1} \in H_{z}^{t} \quad$ and $\quad E\left\langle T_{1}, e(t)\right\rangle=0$. Further $\quad \int_{0}^{t} U(t, r) B(r) u(r) d r \quad$ is $\quad Z_{t}$ measurable and therefore $E\left\langle T_{2}, e(t)\right\rangle=E\left(E\left[\left.\left\langle T_{2}, e(t)\right\rangle\right|_{Z_{t}}\right]\right)=E\left[\left\langle T_{2}, E\left[\left.e(t)\right|_{Z_{t}}\right]\right\rangle\right]=0$. We just have proved that $E\left\langle\hat{\mathrm{y}}_{\mathrm{u}}(\mathrm{t}), \mathrm{e}(\mathrm{t})\right\rangle=0$. Hence $2 \mathrm{E}\left\langle\mathrm{N}(\mathrm{t}) \hat{\mathrm{y}}_{\mathrm{u}}(\mathrm{t}), \mathrm{e}(\mathrm{t})\right\rangle=0$ and
(14) $E\left\|N(t) y_{u}(t)\right\|^{2}=\operatorname{TrN}(t) P(t) N^{*}(t)+E\left\|N(t) \hat{y}_{u}(t)\right\|^{2}$,
where $P(t)$ is the solution of (9)-(10). Let now introduce the cost functional
(15) $\hat{\mathrm{J}}(\mathrm{u})=\varlimsup_{\mathrm{im}}^{\mathrm{t} \rightarrow \infty}{ }_{\mathrm{t}} \frac{1}{\mathrm{t}} \int_{0}^{\mathrm{t}} \int_{0}^{\mathrm{N}} \mathrm{N}(\mathrm{s}) \hat{\mathrm{y}}_{\mathrm{u}}(\mathrm{s}) \|^{2}+\langle\mathrm{K}(\mathrm{s}) \mathrm{u}(\mathrm{s}), \mathrm{u}(\mathrm{s})\rangle \mathrm{ds}$.

If $P(t)$ is bounded on $\mathbf{R}_{+}$we deduce by (14)
(16) $\mathrm{J}(\mathrm{u})=\widehat{\mathrm{J}}(\mathrm{u})+\overline{\lim }_{\mathrm{t} \rightarrow \infty} \frac{1}{\mathrm{t}} \int_{0}^{\mathrm{t}} \operatorname{TrN}(\mathrm{s}) \mathrm{P}(\mathrm{s}) \mathrm{N}^{*}(\mathrm{~s}) \mathrm{ds}$.

Now it is clear that the optimal control in the class $U$, which minimize (15) subject to (11)-(12) is also optimal for our control problem with partial observations (separation principle).
Therefore, we can solve the linear quadratic control problem with complete observations (11)(12), (15). Let us consider the Riccati equation
(17) $R^{\prime}(t)+A^{*}(t) R(t)+R(t) A(t)$
$+N(t) N^{*}(t)-R(t) B(t)[K(t)]^{-1} B^{*}(t) R(t)=0$.
We recall here that a global solution $R(t)$ of (17) is stabilizing for $\{\mathrm{A}: \mathrm{B}\}$ iff $\left\{A-B[K(t)]^{-1} B^{*} R\right\} \quad$ is uniformly exponentially stable. The following result is known:

Proposition $2[4,8]$ Assume $\{\mathrm{A}: \mathrm{B}\}$ is stabilizable and $\{\mathrm{A} ; \mathrm{N}\}$ is either uniformly
observable or detectable. Then the Riccati equation (17) has a unique nonnegative, bounded on $\boldsymbol{R}_{+}$and stabilizing solution $\mathrm{R}(\mathrm{t})$.

Before to prove the main result of this section it is useful to introduce the following approximating systems
(18) $R_{n}^{\prime}(t)+A_{n}^{*}(t) R_{n}(t)+R_{n}(t) A_{n}(t)+N(t) N^{*}(t)-R_{n}(t) B(t)[K(t)]^{-1} B^{*}(t) R_{n}(t)=0$,
(19) $d \hat{y}_{\mathrm{n}}(\mathrm{t})=\mathrm{A}_{\mathrm{n}}(\mathrm{t}) \hat{\mathrm{y}}_{\mathrm{n}}(\mathrm{t}) \mathrm{dt}+\mathrm{B}(\mathrm{t}) \mathrm{u}(\mathrm{t}) \mathrm{dt}+\mathrm{P}(\mathrm{t}) \mathrm{C}^{*}(\mathrm{t})\left[\overline{\mathrm{V}}(\mathrm{t}) \overline{\mathrm{V}}^{*}(\mathrm{t})\right]^{-1} \mathrm{~d} \eta(\mathrm{t}), \hat{\mathrm{y}}_{\mathrm{n}}(0)=\overline{\mathrm{y}}_{0}, \mathrm{n} \in \mathbf{N}$.

Let $Q \in L^{+}(H)$. It is known [5] that (18) (respectively (17)) with the final condition $R_{n}(T)=Q \quad$ (respectively $\quad R(T)=Q$ ) has a unique classical (respectively mild) solution $R_{n}(T, s ; Q)$. Moreover, $\mathrm{Q}_{\mathrm{n}}(\mathrm{T}, \mathrm{s} ; \mathrm{R}) \mathrm{x} \underset{\mathrm{n} \rightarrow \infty}{\rightarrow} \mathrm{Q}(\mathrm{T}, \mathrm{s} ; \mathrm{R}) \mathrm{x}$, uniformly on $[0, T]$. Analogously, the system (19)-(20) has unique strong solution $\hat{\mathrm{y}}_{\mathrm{u}}^{(\mathrm{n})}(\mathrm{t})$, which converges to the unique mild solution $\hat{\mathrm{y}}_{\mathrm{u}}(\mathrm{t})$ of (11)-(12) uniformly on $[0, T]$.
Theorem 3 Assume that $\left\{\mathrm{A}^{*}: \mathrm{C}^{*}\right\}$ is stabilizable and the hypotheses of the above proposition are satisfied. Then the optimal control for the problem (11)-(15) is given by the feedback law $\tilde{\mathrm{u}}(\mathrm{t})=-[\mathrm{K}(\mathrm{t})]^{-1} \mathrm{~B}^{*}(\mathrm{t}) \mathrm{R}(\mathrm{t}) \hat{\mathrm{y}}_{\tilde{\mathrm{u}}}(\mathrm{t})$, where $R$ is the unique bounded and nonnegative solution of (17). The optimal cost is
(20) $\hat{\mathrm{J}}(\tilde{\mathrm{u}})=\overline{\lim }_{\mathrm{t} \rightarrow \infty} \frac{1}{\mathrm{t}} \int_{0}^{\mathrm{t}} \operatorname{TrR}(\mathrm{s}) \mathrm{P}(\mathrm{s}) \mathrm{C}^{*}(\mathrm{~s})\left[\overline{\mathrm{V}}(\mathrm{s}) \overline{\mathrm{V}}^{*}(\mathrm{~s})\right]^{-1} \mathrm{C}(\mathrm{s}) \mathrm{P}(\mathrm{s}) \mathrm{ds}$.

Moreover, the control $\tilde{\mathrm{u}}$ is also optimal for the control problem with partial observations (1)(2), (3) and

$$
\min _{\mathrm{u} \in \mathbf{U}} \mathrm{~J}(\mathrm{u})=\mathrm{J}(\tilde{\mathrm{u}})=\hat{\mathrm{J}}(\tilde{\mathrm{u}})+\overline{\lim }_{\mathrm{t} \rightarrow \infty} \frac{1}{\mathrm{t}} \int_{0}^{\mathrm{t}} \operatorname{TrN}(\mathrm{~s}) \mathrm{P}(\mathrm{~s}) \mathrm{N}^{*}(\mathrm{~s}) \mathrm{ds} .
$$

Proof. Let $R(t)$ be the unique global solution of (17). If $\mathrm{R}_{\mathrm{n}}(\mathrm{s})=\mathrm{R}_{\mathrm{n}}(\mathrm{t}, \mathrm{s}, \mathrm{R}(\mathrm{t}))$ is the solution of (18), then we consider the function $F_{n}(s, x)=\left\langle R_{n}(s) x, x\right\rangle$ which is continuous together its partial derivatives $\mathrm{F}_{\mathrm{n}, \mathrm{s}}, \mathrm{F}_{\mathrm{n}, \mathrm{x}}, \mathrm{F}_{\mathrm{n}, \mathrm{xx}}$ on $[0, \infty) \times \mathrm{H}$. Let $u \in \mathcal{V}$ and $\hat{\mathrm{y}}_{\mathrm{u}}(\mathrm{s})$ be its response. Using Ito's formula for $\mathrm{F}_{\mathrm{n}}(\mathrm{s}, \mathrm{x})$ and the strong solution $\hat{y}_{u}^{(n)}(\mathrm{s})$ of (19) and taking expectations we get

$$
\begin{aligned}
& E\left\langle R_{n}(t) \hat{y}_{u}^{(n)}(t), \hat{y}_{u}^{(n)}(t)\right\rangle-\left\langle R_{n}(0) \bar{y}_{0}, \bar{y}_{0}\right\rangle=-E \int_{0}^{t}\left\|N(s) \hat{y}_{u}^{(n)}(s)\right\|^{2}+\langle K(s) u(s), u(s)\rangle d s \\
&++\int_{0}^{t}\left\|K(s)^{1 / 2}\left[u(s)+[K(s)]^{-1} B^{*}(s) R_{n}(s) \hat{y}_{u}^{(n)}(u)\right]\right\|^{2} d s \\
&+\int_{0}^{t} \operatorname{TrR}_{n}(s) P(s) C^{*}(s)\left[\bar{V}(s) \bar{V}^{*}(s)\right]^{-1} C(s) P(s) d s .
\end{aligned}
$$

We first note that $R_{n}(s) \underset{n \rightarrow \infty}{\rightarrow} R(s)$ uniformly on $[0, t]$. Letting $n \rightarrow \infty$ in the above relation and using the Dominated Convergence Theorem of Lebesgue we get

$$
\begin{gathered}
E\left\langle R(t) \hat{y}_{u}(t), \hat{y}_{u}(t)\right\rangle-\left\langle R(0) \bar{y}_{0}, \bar{y}_{0}\right\rangle=-E \int_{0}^{t}\left\|N(s) \hat{y}_{u}(s)\right\|^{2}+\langle K(s) u(s), u(s)\rangle d s \\
+E \int_{0}^{t}\left\|K(s)^{1 / 2}\left[u(s)+[K(s)]^{-1} B^{*}(s) R(s) \hat{y}_{u}(u)\right]\right\|^{2} d s \\
+\int_{0}^{t} \operatorname{TrR}(s) P(s) C^{*}(s)\left[\overline{\mathrm{V}}(\mathrm{~s}) \overline{\mathrm{V}}^{*}(\mathrm{~s})\right]^{-1} C(\mathrm{~s}) P(\mathrm{~s}) \mathrm{ds} .
\end{gathered}
$$

We make use of the boundedness of $R(t)$ and we easily deduce that

$$
\begin{aligned}
& \hat{\mathrm{J}}(\mathrm{u})=\varlimsup_{\mathrm{\lim }}^{\mathrm{t} \rightarrow \infty} \mathrm{f} \\
& \frac{1}{\mathrm{t}} \int_{0}^{\mathrm{t}} \operatorname{TrR}(\mathrm{~s}) \mathrm{P}(\mathrm{~s}) \mathrm{C}^{*}(\mathrm{~s})\left[\overline{\mathrm{V}}(\mathrm{~s}) \overline{\mathrm{V}}^{*}(\mathrm{~s})\right]^{-1} \mathrm{C}(\mathrm{~s}) \mathrm{P}(\mathrm{~s}) \mathrm{ds} \\
& +\overline{\lim }_{\mathrm{t} \rightarrow \infty} \frac{1}{\mathrm{t}} \mathrm{E} \int_{0}^{\mathrm{t}}\left\|\mathrm{~K}(\mathrm{~s})^{1 / 2}\left[\mathrm{u}(\mathrm{~s})+[\mathrm{K}(\mathrm{~s})]^{-1} \mathrm{~B}^{*}(\mathrm{~s}) \mathrm{R}(\mathrm{~s}) \hat{\mathrm{y}}_{\mathrm{u}}(\mathrm{u})\right]\right\|^{2} \mathrm{ds} .
\end{aligned}
$$

It is not difficult to see that $\tilde{u}(s)=-[K(s)]^{-1} B^{*}(s) R(s) \hat{y}_{u}(u), s \geq 0$ belongs to $U$ and minimize $\hat{J}(u)$ in the class of admissible controls. Obviously, (20) follows by (16). The proof is complete.
