ABSTRACT

This study reveals the way of understanding the usages of pesticides and the development of the distribution process of pesticides in vegetable production in southern part of Bangladesh. In this regard, a descriptive study has been, at first, conducted to understand the insights about the pesticide use. A sample of 152 farmers has been interviewed from different regions of Patuakhali and Barisal districts of Bangladesh. To test the data analysis, ANOVA, KMO statistic, and also factor analysis have been conducted and the result revealed that convenient location and collection process of the pesticides are the most important factors for the farmers to produce vegetable.

Key words: ANOVA, KMO statistic, Factor analysis, Distribution process, Bangladesh

INTRODUCTION

In Bangladesh as the colonial rulers did not obviously pay attention to the well-being of the people, food production could not keep pace with the ever increasing population. As a result, food shortages and malnutrition have become chronic problems. Malnutrition is a serious public health problem in Bangladesh. It retards child growth, increases the risk and duration of illness, reduces work output, and slows social and mental development. Nutrition survey in rural Bangladesh reports that average intake meat only 80% of calories, 58% of vitamin A, 50% of riboflavin and 51 % of the vitamin requirement (BINFS 1982). Rice, the staple food, contributes more than 80% of our daily food intake. Although vegetable form an indispensable part of our daily diet, they contribute a very small percentage of total food intakes partly due to short supply, production, and health unawareness. The availability of vegetable per head per day is only 82 g. whereas the nutritionists suggest that on an average, a person should eat at least 235 g. of vegetable a day to maintain good health. Though the trends in vegetable production are increasing in Bangladesh in the recent period, per capita consumption of vegetable is very low (about 32 gm/day/person) compared to neighboring countries, like in Nepal (42 g), India (135 g) and Srilanka (120 g) (Rampal and Gill 1990). Helen Keller International's (HKI) recent national vitamin A survey in rural Bangladesh showed that children from households without a home garden were at greater risk of vitamin A deficiency than children of households with a home garden. So, intensive vegetable production is needed for

nutritional security, employment generation, and higher farm income, better export potential and lower depending on cereal consumption (Elias and Hussain, 1994). Therefore, the planners should refer vegetable also a staple food as rice does. So, if we can grow more vegetable, the problem of existing acute malnutrition and food shortages might be overcome to a significant extent. Under the socioeconomic condition, an improved natural farming pesticide may be used an important pesticide in improving vegetable production. The area under vegetable cultivation in Bangladesh is small. Bangladesh is facing a chronic food shortage which is now approaching 2 million mg. per year. For the last few decades, the government has been trying in vain to become self-sufficient in food production. When the planners refer to the food they mean rice only, they are not giving attention to improve the production of crops like vegetable. For the planners, the term food should also include fruits and vegetable, which are indispensable for maintaining good health. In fact, existing acute malnutrition problems could be overcome by increasing vegetable production. To meet the minimum daily requirement of vegetable, i.e. 235 g. per head per day, we should increase vegetable production by about 7.5 million mg.—An increase of 300% (A. R. Chowdhury, 2008).

On the other hand, Bangladesh does not produce any active ingredients which are used in vegetable production, it only imports and formulates. The marketing channel of pesticides in Bangladesh consists of pesticide companies, distributors, wholesalers,

wholesaler-cum-retailers, retailers and farmers (Sabur and Moila, 2000). At the top, there exist approximately 66 officially registered companies, with 6 of these being multinational in nature. Distributors buy almost all of their products from pesticide companies. However, the pesticide companies also directly sell to wholesalers. Distributors, in turn, sell their products to the wholesalers-cum-retailers. Retailers, in turn, sell their product to farmers, but farmers frequently buy directly from the distributors as well as wholesalers. That's why the cost of the pesticide is increasing; as a result the cost of the vegetable is also increasing. So, for the better production and distribution of the vegetable, it is necessary to implement a proper marketing process of all the inputs of the vegetable (Dasgupta, S. *et al*, 2005).

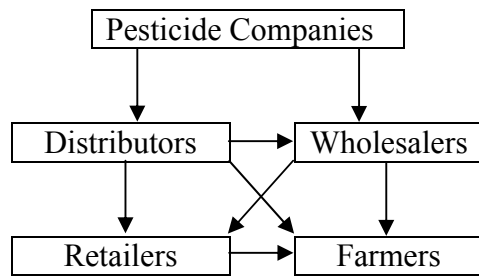

Figure 1 A Simplified Representation of Pesticide Marketing Channels in Bangladesh

Like many developing countries, Bangladesh has promoted the use of pesticides to expand agricultural land and increase output per acre. As a consequence of this expansion policy, pesticide use has more than doubled since 1992, rising from 7,350 metric tons to 16,200 metric tons in 2001. An FAO analysis of pesticide composition revealed high shares of toxic chemicals which have known to cause cancer, genetic damage, fetal damage, and severe allergic responses in exposed populations (for example, carbamates and organophosphates in insecticides, and dithiocarbamates and inorganic in fungicides) (Zahm, Ward and Blair, 1997). Many pesticides used in Bangladesh are also banned or restricted under international agreements (Meisner, 2004; NOVIB, 1993; SOS-arsenic.net, 2004; SUNS, 1998). Pesticide suppliers in Bangladesh even continue to sell the 12 particularly controversial pesticides known by activists campaigning worldwide as the "dirty-dozen" (SUNS, 1998; SOS-arsenic.net, 2004). In addition, several studies have shown that inadequate product labeling and users' lack of information have led to widespread overuse and misuse of dangerous pesticides. Anecdotal evidence suggests that the consequence of these practices is numerous, with pesticide poisonings abound (Ramaswamy, 1992).

OBJECTIVES

To survive the people of Patuakhali District with sufficient vegetable our research has given emphasis on the following objectives:

- [1] To find out why the vegetable are not produced a lot (finding the factors affecting distribution process of pesticides)
- [2] To find out why they purchase vegetable from other regions
- [3] To give proper direction of getting and using the proper pesticides to their vegetable

METHODOLOGY

The research was conducted by both primary and secondary data and pertinent literature survey. At first a descriptive study was conducted to understand the insights of farming the land in the purpose of vegetable production and about the pesticides collection. Then the study will conduct through a structured questionnaire with measurement scaling by considering a sample size of 152 farmers. A 5-point structured questionnaire (1: Exactly not, 2: Not, 3: Somewhat know, 4: Yes and 5: Exactly know) is developed to know the perception of the farmers about the distribution process of the pesticides to this southern part of Bangladesh. The data has been collected from the farmers of Dumki Upazilla, Galachipa Upazilla and Distributors Offices of Patuakhali District and Some regions of Barisal district from January to December 2012. SPSS¹ Software will be used to analyze the data. ANOVA and KMO statistic are done to simplify the significance of the research. The statistical tool, factor analysis² was conducted to identify the important factors from the responses of the 152 sample farmers regarding 8 variables which account for their inter-correlation. A principal factor analysis with an orthogonal rotation (Varimax) by using the SPSS statistical package was performed on the survey data and was used to separate the factors.

DATA ANALYSIS

A total 4,431.4 decimal land of different land owners of Dumki Upazilla, Galachipa Upazilla of Patuakhali District and some regions of Barisal District have been surveyed. The total production of these lands is 1,90,375.20 Kg where the average production is 43.95 Kg/decimal. Most of the farmers produce the vegetable only for their family consumption due to shortage of sufficient and good pesticides. Most of the pesticide distributors of these regions are retailers, but there are also some wholesalers and dealers. They mainly sell packaged pesticides with list price of the goods. Sometimes they also sell their products at discounted price. So, the farmers are only purchased their necessary pesticides from the retailers (with the) for their use of pesticides in the field. The following are the results.

Table 1 Distributor of Pesticides

Type of Sellers	Frequency	Percent	Valid Percent	Cumulative Percent
Dealer	48	31.6	31.6	31.6
Retailer	94	61.8	61.8	93.4
Local agricultural farm	2	1.3	1.3	94.7
Private organization	8	5.3	5.3	100.0
Total =	152	100.0	100.0	

From Table 1 it is shown that the percentage of farmers who collect pesticides from retailers accounted for 61.80%. They also purchase the pesticides from dealers, private organizations and also from local agricultural farms.

Table 2 describes the information regarding pesticides where most of the farmers collect the periodical information accounts for 69.70%.

Table 2 Information regarding pesticides

Scaling Point	Frequency	Percent	Valid Percent	Cumulative Percent
Sometimes Know	38	25.0	25.0	25.0
Yes (All the time)	8	5.3	5.3	30.3
Periodically know	106	69.7	69.7	100.0
Total =	152	100.0	100.0	

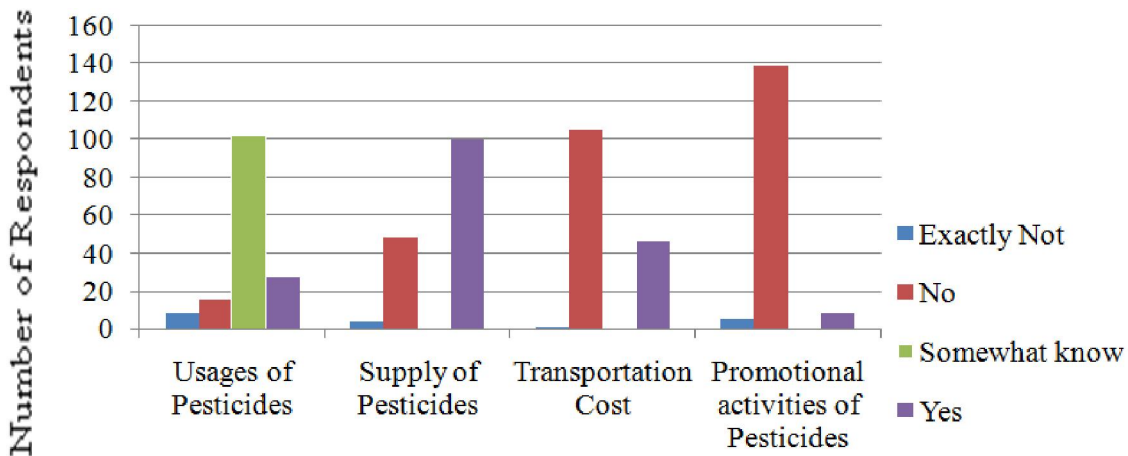

Figure 5 Usages, Supply, Transportation Cost and Promotional activities of Pesticides

Table 5 shows the 5 relative factors associated with the pesticide distribution process to the southern part of Bangladesh. It is shown that the farmers do not exactly know about the usages of the pesticide to their vegetable field. They only somewhat know about their previous farming experience of their field. Out of 152 respondents only 100 farmers said that the pesticides are supplied properly to their hand. But about 32% farmers said that they are not properly supplied. In case of transportation cost, almost 30% of total respondents said that they have to pay the transportation cost for the collection of the pesticides. In case of 91% of the total respondents said that

there are no promotional activities for their pesticides selling. The research is tested in Table 6 and Table 7.

Table 6 ANOVA Test

Model		Sum of Squares	Df	Mean Square	F	Sig.
1	Regression	7.930	7	1.133	2.218	.037(a)
	Residual	61.791	121	.511		
	Total	69.721	128			

a Predictors: (Constant), Type of Pesticides, Promotional activities of pesticides, Supply of Pesticides, Information regarding Pesticides, Distributor of Pesticides, Transportation Cost, Collection Process

b Dependent Variable: Usages of Pesticides

Table 3 illustrates the collection process of the pesticide where 17 farmers didn't make any comment. About 86% of the total farmers said that their make their payment in the face value of the pesticide. Also there are some farmers who collect the pesticide through down payment and discounted price.

Table 3 Collection Process

Price	Frequency	Percent	Valid Percent	Cumulative Percent
Book Value	130	85.5	96.3	96.3
Discounted Price	4	2.6	3.0	99.3
Down payment price	1	.7	.7	100.0
Total	135	88.8	100.0	
Missing	17	11.2		
Total=	152	100.0		

Table 4 Type of Pesticides

Type of Pesticides	Frequency	Percent	Valid Percent	Cumulative Percent
Non-packaged pesticides	6	3.9	4.4	4.4
Packaged pesticides	130	85.5	95.6	100.0
Total	136	89.5	100.0	
Missing	16	10.5		
Total =	152	100.0		

From ANOVA Test, it shows that the table sig. value 0.05 is greater than the calculated sig. value 0.037. So, it rejects the null hypothesis at 5% level of significance. It means there was a significant correlation between dependent variable and independent variables. Therefore, usages of pesticides depend on the distribution process of pesticides to the different region in the southern part of Bangladesh.

Table 7 KMO and Bartlett's Test

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		.509
Bartlett's Test of Sphericity	Approx. Chi-Square	67.348
	Df	28
	Sig.	.000

The factor analysis shows that the three factors with eigenvalue greater than one (Table 1). These three factors are identified out of 8 variables explain about 53% variability of the data. The factor analysis of 8 variables with 152 sample is found adequate (KMO test result =0.509 > 0.50) and valid (Bartlett's test of sphericity indicates a significance level of 0.000). The communalities of the variables that constituted the factors are found very strong which indicates robust relationships among the variables (Appendix 1).

Table 8 Eigen value, Relative Variance (%) and Cumulative Relative Variance (%) of the Factors

Factors	Factor Name	Eigen value	% of Variance	Cumulative %
1	Convenience	1.611	20.143	20.143
2	Motivation	1.508	18.848	38.992
3	Demand and Supply	1.123	14.036	53.027

Extraction Method: Principal Component Analysis

Also it can be noted that the first factor (Convenient) appears to be the most important as it explains 20.143% (σ^2) of the variability. Other factors are Motivation ($\sigma^2=18.848\%$) and Friendly ($\sigma^2=14.036\%$).

Table 9. Component Matrix (a)

Variables	Factor		
	First	Second	Third
Distributor of Pesticides	.703	-.121	-.093
Information regarding Pesticides	.143	-.642	.248
Usages of Pesticides	-.499	-.288	.433
Supply of Pesticides	-.111	.328	.544
Transportation cost	-.359	.607	.079
Promotional activities of pesticides	.284	.644	.292
Collection Process	.742	.228	.087
Type of Pesticides	-.275	.236	-.685

Extraction Method: Principal Component Analysis 3 components extracted

FIRST FACTOR: CONVENIENCE

It appears that convenient location is the most important factor in the eyes of respondents (farmers) for the pesticides collection of their vegetable production. Based on their responses it may be deduced that the respondents believe that distributor of the pesticides location and collection process are the important two variables (Table 4). Both of the variables have factor loading of more than 0.50. This clearly shows the relative strength of these individual variables. Therefore, presence of convenient location of the pesticides outlets is very important factor for two reasons: (a) They have the highest factor loadings and (b) It saves the transportation cost and time too.

S.N	Name of the variables	Name of the Factor
1	Distributor of Pesticides, Collection Process	Convenience
2	Transportation cost, Promotional activities of pesticides, Type of Pesticides	Motivation
3	Information regarding Pesticides, Usages of Pesticides, Supply of Pesticides	Demand and Supply

SECOND FACTOR: MOTIVATION

The second most important factor is motivation to the farmers for the pesticides marketing in southern part of Bangladesh for their vegetable production. The variables (Transportation cost, promotional activities of pesticides and types of pesticides) under this factor also have a relatively high factor loading of more than 0.50. The presence of motivation of the farmers about pesticides leads the proper usages and purchases the pesticides in the proper time.

THIRD FACTOR: DEMAND AND SUPPLY

The last important factor in the eyes of the respondents (farmers) for the pesticide collection of their vegetable production is demand and supply of pesticide. Two of the variables under this factor have less factor loadings (less than 0.050) are: information regarding pesticides, usages of pesticides. The only supply of pesticides variable has more factor loadings (more than 0.50). This means the supplier of the pesticides can consider this factor, but if they do then it will be better for the company as well as the farmers to use in their vegetable field.

CONCLUSION AND RECOMMENDATION

Bangladesh is a developing country of which most of poor people are living in the southern part of Bangladesh. The income levels of these people are very small amount that's why they didn't use the necessary things in the proper time. They are just living from hand to mouth. Even they just produce the products in their daily lives with raw pesticides and fertilizers. Even they purchased the daily

goods which come from the other regions because of the lower price rather than their own produced goods because of charging a higher cost. So, if the distribution process of pesticides are not well developed then it is impossible to good to these people. The following recommendations are made for the development of the proper distribution process of the pesticides:

- One cost-effective approach would be to increase awareness and training at the wholesaler or retailer level, where the effort has its greater reach to make understanding of the farmers about the usages of the pesticides.
- The outlets of pesticides should be in a convenient location because of the easy collection process of the pesticides. It will also reduce the total production cost of the vegetable.
- There should be promotional activities for the pesticides. It will help the farmers more interested to purchase the pesticides and to use in their vegetable field which will increase the total production of the vegetable.
- There are not sufficient markets in their convenient location for which they have to sell their goods to the middleman; as a result they deprived from the actual profit. So, if the government can take the necessary steps regarding this issue, then the farmers will also grow their interest to produce more vegetable in their fields.
- The different media (broadcasting channels) should broadcast the issue of the pesticides usages (amount of pesticides per decimal).
- Most of the pesticides buyers are the poor buyers. So, if there is a chance to return the flawed and unused pesticides, then the farmers would be more beneficial in some context.
- The distribution process of the pesticides should be directed from the organizational distributors to the farmers so that the farmers can get the pesticides in fair price.

NOTES

- SPSS refers to the Statistical Package for Social Sciences.
- Factor analysis is a type of analysis used to discern the underlying dimensions or regularity in phenomenon. Its general purpose is to summarize the information contained in a large number of variables into a smaller number of factors. It is an interdependence technique in which all variables are simultaneously considered.

APPENDIX

Appendix 1

Factors related to the distribution process of the Pesticides marketing and their Communalities

Variable Code	Variable Name	Extraction
V1	Distributor of Pesticides	.518
V2	Information regarding Pesticides	.494
V3	Usages of Pesticides	.519
V4	Supply of Pesticides	.417
V5	Transportation cost	.503
V6	Promotional activities of pesticides	.581
V7	Collection Process	.610
V8	Type of Pesticides	.600

Extraction Method: Principal Component Analysis.
