Abstract

Introduction: The experiment was aimed to investigate (i) the comparative efficacy of papaya leaves suspension (PLS) and doxycycline on bacterial load and blood constituents on *E. coli* inoculated Japanese quail, (ii) the effect of PLS on live body weight, egg production and egg quality (Egg weight, egg shape index, shell plus membrane weight, shell plus membrane thickness, haugh unit, albumen index and yolk index) of Japanese quail.

Materials and Methods: 120 female Japanese quails ten days old were randomly assigned into four groups with three replications and grouped as control group (T₀), *E. coli* treated group (T₁), *E. coli* plus PLS (0.25%) treated group (T₂) and *E. coli* plus doxycil-vet powder (1g/2lit) treated group (T₃) for the aim (i). Ten days old 60 female Japanese quails were randomly assigned into two groups named T₀ (control diet) and T₁ (0.25% PLS) with three replications to fulfill the aim (ii).

Result: (i) microbial load significantly (P<0.05) decreased in T₂ & T₃ group where significantly (P<0.05) increased in T₀ and T₁ group. TEC, Hb, PCV & ESR in different treatment groups were almost similar and the differences were statistically non-significant (P>0.05) except TLC which was statistically significant (P<0.05) and the highest TLC was recorded in T₂ group.

(ii) The body weight of T₀ and T₁ at 65th day were 164.95 and 182.32 g respectively which was statistically significant (P<0.05). The Hen-day-egg production (HDEP) observed for 15 days were 68.29% and 73.10% in T₀ and T₁ group respectively which statistically significant (P<0.05). In the treatment groups the external and internal quality of eggs (Egg weight, egg shape index, shell plus membrane weight, shell plus membrane thickness, haugh unit, albumen index and yolk index) were almost similar and the differences were statistically non-significant (P>0.05).

Conclusion: It may concluded that papaya leaf (*Carica papaya*) suspension have antimicrobial effect and effect on blood constituents, growth performance and egg production of Japanese quail.

Keywords: *Coturnix japonica*, *Carica papaya*, *E. coli*, Hematology, Body weight and egg production.

Introduction

For a long time, the poultry industry in Bangladesh has been dominated largely by broiler and egg layer chicken farming. In the recent past, however, rearing of Japanese quail (*Coturnix japonica*) for meat and egg production has fast-gained prominence in the country. Japanese quails are prone to almost all diseases that are seen in chickens and other poultry breeds. Quail are susceptible to a variety of bacterial, fungal and parasitic diseases. Among these diseases avian colibacillosis and salmonellosis are considered to be the major bacterial diseases in the poultry industry world-wide. Avian colibacillosis has been noticed to be a major infectious disease in birds of all ages. It is caused by a bacterium called *Escherichia coli*.

Food safety has become one of the most important public health issues in Bangladesh. Nowadays people become more health conscious. Common pathogenic bacteria that associated with food borne diseases include *E. coli*.¹ Quail eggs and meat is gradually gaining popularity in Bangladesh. *E. coli* infection is considered to be the major bacterial diseases in quail. It can be controlled with antibiotic therapy but a significant increase in drug-resistant strains of *E. coli* has complicated the problem in the poultry industry. Also antibiotics as feed additive can increase abdominal

fat in poultry and increase risk of heart disease in consumers.²

So, we need to quickly replace of antibiotics with other options. These new options should be inexpensive and available in everywhere as well as healthy for human society. It is thought that medicinal plants are a good alternative for this purpose. Since ancient times, medicinal plants play important role in health management of traditional poultry production.³ The extracts of papaya leaves could inhibit the growth of *Rhizopus stolonifer*.⁴ Antibacterial activities of papaya leaf extracts on pathogenic bacteria was observed in this study. This experiment was conducted to study the antibacterial activity of papaya leaves suspension against *E. coli* infection in quail in comparison with therapeutic dose of doxycycline hydrochloride. Growth promoting activity and effect on egg production of the herb, "*Carica papaya*", was also studied.

The general objective of this study was to know the effect of papaya leaves suspension in Japanese quail with the following specific objectives:

1. To investigate the antibacterial and hematological effects of papaya leaf on *E. coli* inoculated Japanese quails
2. To observe the effect of papaya leaf on body weight and egg production performances in Japanese quails.

Materials and Methods

1. The experiment was conducted at the experimental shed under the Department of Physiology and Pharmacology and microbial test was performed at microbiology laboratory of the Department of Microbiology, HSTU, Dinajpur, Bangladesh. The experiment was performed for a period of 25 days from 3rd October to 28th October, 2017 to investigate the comparative effect of PLS and doxacil-vet powder suspension on *E. coli* inoculated Japanese quail. 10 days old 120 female Japanese quail were assigned into four treatments with three replications (each containing 10 quails) per treatment. They were designated as **T₀** = Negative control group (Basal diet), **T₁** = Positive control group (Basal diet + *E. coli*), **T₂** = PLS group (Basal diet + *E. coli* + 0.25% Papaya leaves suspension) and **T₃** = Doxycycline group (Basal diet + *E. coli* + Doxacil-Vet powder @ 1 g per 2 litre water). All groups were supplied *E. coli* orally except T₀ group and after 24 hours T₂ & T₃ groups were treated with PLS (0.25%) and doxacil-vet powder suspension (1g/2lit) respectively. EMB agar was used for counting CFU (colony forming unit).

Statistical analysis: The collected data were recorded and analyzed by one way ANOVA following Duncan post hoc test using SPSS program version 20 software to find out the difference among the treatments.

2. The experiment was conducted at the experimental shed under the Department of Physiology and Pharmacology and the egg quality determination was performed at Dairy and Poultry Science laboratory under the Department of Dairy and Poultry Science, HSTU, Dinajpur. The experiment was performed for a period of 55 days from 3rd October to 29th November, 2017 to observe the effects of papaya leaves suspension on body weight and egg production of Japanese quail. 10 days old 60 female Japanese quail were assigned into two groups with three replications containing 10 quails in each replication and designated as **T₀** = Control group (Basal diet) **T₁** = PLS group (Basal diet plus 0.25% Papaya leaves suspension). Young papaya leaves were collected and washed with fresh water. Before chopping it into small pieces, it was soaked with cotton for removing the adhesive water. Then the leaf was chopped into small pieces and was mashed with the help of pestle and mortar. Leaf juice was collected by squeezing mashed leaf. Then it had been produced 0.25% of suspension of grinded papaya leaf with distilled water.

Recording of Body Weight

The quails were weighed just before to the commencement of treatment at the 20th day of age and then every 15 days interval body weight was recorded. Last body weight was recorded at the end of the experimental period (65th day of age) with the help of digital balance.

Hen Day Egg Production: Egg production percent was determined replication wise by the following formula.

Hen day egg production (HDEP) (%)

$$= \frac{\text{No. of eggs laid}}{\text{Total no. of days}} \times 100$$

Egg Weight: Weight of each egg was recorded before quality determination by using a digital balance.

Egg Shape Index: Measurements of egg length and width were taken with a caliper to the nearest 0.01 mm. The egg shape index was determined from these measurements according to the following formula.^{5,6}

$$\text{Egg shape index} = \frac{\text{Egg width}}{\text{Egg length}} \times 100(\%)$$

Albumen Index: The albumen index was determined according to the following formula.⁷

Albumen index =

$$\frac{\text{Average height of thick albumen}}{\text{Average diameter of thick albumen}} \times 100(\%)$$

Yolk Index: The yolk index was determined by the following formula.⁸

$$\text{Yolk index} = \frac{\text{Average height of yolk}}{\text{Average diameter of yolk}} \times 100(\%)$$

Haugh Unit: Haugh unit (HU) of egg was calculated according to following formula. HU=100log (H+7.57 - 1.7W^{0.17})

Shell plus membrane weight and thickness: Immediately after breaking the eggs, the egg shell was soaked with cotton to remove adhesive albumin and egg shell plus membrane weight was recorded with the help of a digital balance. Egg shell plus membrane thickness (mm) was measured by screw gauge. Three measurements were taken from three different locations of each shell; two reading from the waist region and one reading from each end of egg.

Statistical Analysis

Data were analyzed by independent-samples t-test. All analyses were performed by SPSS program version 20. The level of significance was set when the P value is <0.05.

Results

This study showed that, microbial load in feces was significantly differed among the treated groups. Microbial load significantly (P<0.05) increased in T₀ (negative control) and T₁ (positive control) group. Microbial load significantly (P<0.05) decreased in T₂ group supplied with 0.25% papaya leaves suspension and doxacil-vet powder suspension. (Table 1).

The values of TEC, PCV, Hb and ESR in all treated groups and control group were more or less similar and within the normal range at 22nd, 27th and 32nd day of age. These values showed a little fluctuation but were not statistically significant (P>0.05). The values of TLC of T₀ (Basal diet) and T₃ (*E. coli* plus doxacil vet powder) group are more or less similar followed by same superscripts in the same column. But in T₁ (Basal diet plus *E. coli*) and T₂ (*E. coli* plus PLS) group, the values are differed followed by different

superscripts in the same column. The values are also differed between columns among the treated groups. The lowest TLC value (5851 ± 58.65) was recorded from T₂ group at initial stage of experimental period and the highest TLC value was also recorded from T₂ group at last stage of experimental period. The TLC value increased in the group (T₂) fed with 0.25% papaya leaves suspension. (Table 2).

There were a significant ($P < 0.05$) increase in body weight in T₁ (papaya leaf suspension) group than the T₀ (Basal diet) group. Mean body weights at 20th day of age were 38.85 and 37.79 grams where 164.95 and 182.32 grams mean body weights were found at 65th day of age for T₀ and T₁ groups respectively. Birds treated with papaya leaf suspension (T₁ group) had the highest final body weight compared to the birds fed control diet (T₀). (Table 3) The Hen-day-egg production (HDEP) observed for 15 days in two dietary treatments were statistically significant ($P < 0.05$). Result indicated (Table 4) that the feeding of papaya leaf suspension in the drinking water of laying quail has significant effect on egg production. Quails treated with papaya leaf suspension (T₁ group) showed HDEP (%) 73.10 where

birds of control diet (T₀ group) showed 68.29 HDEP (%).

Egg weight, egg shape index, shell plus membrane Weight, shell plus membrane thickness, haugh unit, albumen index and yolk index were presented in (Table 5). It was observed that egg weight, egg shape index, shell plus membrane weight, shell plus membrane thickness, haugh unit, albumen index and yolk index of the eggs laid by quails supplied papaya leaf suspension and control diet were almost similar during experimental period and differences were non-significant. These results indicated that the experimental birds supplied with papaya leaf suspension had no effect on external and internal qualities of egg. However, egg weight and haugh unit slightly improved in the group (T₁) supplied with papaya leaf suspension than the group (T₀) supplied with normal diet. These findings showed dissimilarities with previous study.⁹ They found that diets supplemented with papaya latex had significantly increased shell thickness, egg shape index and haugh unit in eggs of Dokki₄ hens. These results agree with them in findings of no effect on shell weight, yolk index and albumen index.

Discussion

In current study, microbial load significantly (P<0.05) decreased in T₂ group supplied with 0.25% papaya leaves suspension. Previous study showed that papaya leaves have antibacterial activity.⁴

Papaya leaf extracts were tested against *Bacillus stearothermophilus*, *Listeria monocytogenes*, *Pseudomonas sp.* and *Escherichia coli* by agar diffusion method in that study.

The TLC value increased in the group (T₂) fed with 0.25% papaya leaves suspension which agrees with the findings of other studies.⁹ They showed that WBCs were significantly (P<0.05) increased with addition of

papaya latex than those fed control diet experimented on hens and cocks of Dokki⁴ strain.

The increase in WBCs in treated groups might also be concluded leukocytes count. This can be attributed mainly to the antibacterial, antifungal and antioxidant functions of papaya latex. Previous study showed that papaya enzyme increase immune system function.¹⁰ The white blood corpuscles a good indicator of increasing the immunity efficiency.¹¹

There were a significant (P<0.05) increase in body weight in papaya leaf suspension group than the basal diet group. This weight gain due to papaya leaf containing papain enzyme. Papain is a protease enzyme that hydrolyzes proteins to short peptides which are the

key factors to increase protein digestibility, fast absorption and helps to increase growth factors.¹⁵ Previous study also showed significant ($P<0.05$) body weight gain for Dokki⁴ laying hens with different levels of papaya latex.⁹ These findings were also confirmed upon examination of papaya latex on rabbits.¹²⁻¹⁴

The experimental birds supplied with papaya leaf suspension had no effect on external and internal qualities of egg. However, egg weight and haugh unit slightly improved in the group supplied with papaya leaf suspension than the group supplied with normal diet. These findings showed dissimilarities with previous study.⁹ They found that diets supplemented with papaya latex had significantly increased shell thickness, egg shape index and haugh unit in eggs of Dokki⁴ hens. These results agree with them in findings of no effect on shell weight, yolk index and albumen index.

Conclusion

From the current experimental data, it may concluded that papaya leaf (*Carica papaya*) suspension have antimicrobial effect and effect on blood constituents, growth performance and egg production of Japanese quail. Papaya leaf can also be considered as leukocyte enhancer, efficient growth promoter and remarkable role on egg production in Japanese quail.
