## REFERENCE DATA OF PRESSURE DISTRIBUTION ON THE SURFACES OF AIRFOILS HAVING THE NAMES BEGINNING WITH THE LETTER C

**Abstract:** The results of the computer calculation of air flow around the airfoils having the names beginning with the letter C are presented in the article. The contours of pressure distribution on the surfaces of the airfoils at the angles of attack of 0, 15 and -15 degrees in conditions of the subsonic airplane flight speed were obtained.

**Key words:** the airfoil, the angle of attack, pressure, the surface.

**Language:** English

### Introduction

Creating reference materials that determine the most accurate pressure distribution on the airfoils surfaces is an actual task of the airplane aerodynamics.

### Materials and methods

The study of air flow around the airfoils was carried out in a two-dimensional formulation by means of the computer calculation in the *Comsol Multiphysics* program.

The airfoils in the cross section were taken as objects of research [1-14]. In this work, the airfoils

having the names beginning with the letter *C* were adopted. Air flow around the airfoils was carried out at the angles of attack ( $\alpha$ ) of 0, 15 and -15 degrees.

The flight speed of the airplane in each case was subsonic. The airplane flight in the atmosphere was carried out under normal weather conditions. The geometric characteristics of the studied airfoils are presented in the Table 1. The studied geometric shapes of the airfoils in the cross section are presented in the Table 2.

**Table 1. The geometric characteristics of the airfoils.**

### Results and discussion

The calculated pressure contours on the surfaces of the airfoils at the different angles of attack are presented in the Figs. 1-51.

The calculated magnitudes on the scale can be represented as the basic magnitudes when comparing the pressure drop under conditions of changing the angle of attack of the airfoils.

The optimal airfoil should have good aerodynamic characteristics, i.e. low drag and high lift. The modified version of the CHEN airfoil is subjected to less negative pressure at the different angles of attack. The pressure difference near the upper and lower surfaces of the CJ 2 airfoil is approximately 172 kPa, i.e. it varies by more than 20 times. This indicates a large lift of the airplane wing.

In conditions of the airplane's descent, maximum pressure of -180 kPa acts on the CJ 2 airfoil.

The CSS airfoil is subjected to a minimum pressure of -11.9 kPa at the similar negative angle of attack.

Changing the angle of attack of the Chen high lift airfoil to 15 degrees is accompanied by pressure of -19.2 kPa, which is the minimum pressure magnitude for all considered airfoils.

The minimum negative pressure magnitude was determined in conditions of horizontal flight of the airplane on the upper surface of the CAST 10-2/DOA 2 transonic airfoil. Also, the minimum drag magnitude at the leading edge was calculated for this airfoil. This indicates the most favorable conditions for the airplane flight.

During the airplane maneuvers, the leading edge of the airfoils is subjected to both positive and negative pressures.

The maximum increase in pressure on the leading edge occurs at the angle of attack of -15 degrees for some airfoils:

- CAST 10-2/DOA 2 transonic airfoil;
- Cheesman 25-1,00-10;
- CHEN, Chen high lift airfoil;
- CJ 1, CJ 2, CJ 4, CJ 5;

- CURTISS CR-1.

The shape of the cap 21 symmetrical airfoil ensures the occurrence of the same magnitude of negative pressures on the upper and lower surfaces at the angles of attack of 15 and -15 degrees, respectively.

The maximum increase in pressure on the leading edge occurs at the angle of attack of 15 degrees for the remaining airfoils.

### Conclusion

The least drag force during horizontal flight of the airplane occurs in the airfoils having the leading edge radius of 0.91%. The greatest lift force acts at the maximum thickness of the airfoil of 5.6% at 20% of the chord. These requirements are met by the CJ 2 and CAST 10-2/DOA 2 airfoils.
