REFERENCE DATA OF PRESSURE DISTRIBUTION ON THE SURFACES OF AIRFOILS HAVING THE NAMES BEGINNING WITH THE LETTER L

Abstract: The results of the computer calculation of air flow around the airfoils having the names beginning with the letter L are presented in the article. The contours of pressure distribution on the surfaces of the airfoils at the angles of attack of 0, 15 and -15 degrees in conditions of the subsonic airplane flight speed were obtained.

Key words: the airfoil, the angle of attack, pressure, the surface.

Language: English

Introduction

Creating reference materials that determine the most accurate pressure distribution on the airfoils surfaces is an actual task of the airplane aerodynamics.

Materials and methods

The study of air flow around the airfoils was carried out in a two-dimensional formulation by means of the computer calculation in the *Comsol*

Multiphysics program. The airfoils in the cross section were taken as objects of research [1-27]. In this work, the airfoils having the names beginning with the letter L were adopted. Air flow around the airfoils was carried out at the angles of attack (α) of 0, 15 and -15 degrees. Flight speed of the airplane in each case was subsonic. The airplane flight in the atmosphere was carried out under normal weather conditions. The geometric characteristics of the studied airfoils are

Results and discussion

The calculated pressure contours on the surfaces of the airfoils at the different angles of attack are presented in the Figs. 1-26. The calculated values on the scale can be represented as the basic values when comparing the pressure drop under conditions of changing the angle of attack of the airfoils.

26 airfoils of the LOCKHEED, LNV, LINDNER, etc. series were considered. All airfoils had camber of the various value. Thus, all airfoils were asymmetrical.

The drag was determined from the calculated pressure contours on the leading edge of the airfoils. The lower the calculated pressure on the edge, the better the aerodynamic characteristics of the airplane wing. Positive pressure occurs on the leading edge during horizontal flight. The change in the pressure values varies within 0.17 kPa. The slight change in pressure does not give an idea of the more favorable airfoil configuration. Therefore, the lift to drag ratio of the airplane wing can be determined from the pressure distribution area. However, the minimum pressure value (6.42 kPa), and hence the drag coefficient, was determined for the LOCKHEED C-141 BL958,89 airfoil, and the maximum pressure value (6.59 kPa) was determined for the LINDNER2 airfoil.

With an increase in the contact area of the airfoils with air flows, positive pressure increases and negative pressure arises on the leading edge and on the

upper and lower surfaces. This happens under conditions of the airplane maneuvers. The maneuvers are climb and descent of the airplane. In this case, the maximum value of negative pressure was determined on the leading edge of the airfoil. The maximum and minimum values were identified after analyzing the calculated pressures values on the leading edge. Pressure of -68.1 kPa acts on the LINDNER2 airfoil at the positive angle of attack, and pressure of -67.6 kPa acts on the LDS-2 airfoil at the negative angle of attack, which is the highest value of pressures of all calculated values. The minimum pressures values of -27.3 kPa and -6.04 kPa were determined for the LNV109A and lrn1007 airfoils at the positive and negative angles of attack, respectively. Thus, the LNV109A and lrn1007 airfoils have the best aerodynamic properties.

Let us consider these airfoils in detail. The values of the maximum camber of both airfoils are the same and are about 6% relative to the chord length. However, under conditions of the airplane climb, the drag decreases with the large radius of the leading edge of the airfoil. This phenomenon is provided by the airfoil with the small radius of the leading edge during the airplane descent.

The LINDNER2 and LDS-2 airfoils (where high pressure occurs) have the opposite geometric parameters compared to the geometric parameters of the LNV109A and lrn1007 airfoils.

Conclusion

The calculation results make it possible to compare the aerodynamic characteristics of the airplanes wings of the various configurations. Since the large drag on the leading edge reduces the aerodynamic characteristics of the airplane wing, the purpose of this study was to determine and analyze the airfoils that are subjected to minimal pressures during horizontal flight and maneuvers of the airplane. According to this indicator, some airfoils were

identified (LINDNER2, LDS-2, LNV109A and lrn1007). After comparing these airfoils, it was concluded that the maximum camber of the airfoil during the airplane maneuvers should vary in the range from 3% to 6% relative to the chord length, and the radius of the leading edge during climb and descent of the airplane should be at least 3.5% and 0.2%, respectively. These geometric parameters of the airfoils improve the aerodynamic characteristics of the airplane.
